## Abstract

Efficient and accurate modeling of the coupled thermal-hydraulic-mechanical-chemical (THMC) processes in various rock formations is indispensable for designing energy geo-structures such as underground repositories for high-level nuclear wastes. This work focuses on developing and verifying an implicit finite element solver for generic coupled THMC problems in geological settings. Starting from the mass, momentum, and energy balance laws, a specialized set of governing equations and a thermoporoelastic constitutive model is derived. This system is then solved by an implicit finite element (FE) scheme. Specifically, the residuals and the Jacobians are scripted in a user-defined element (UEL) subroutine which is then combined with the general-purpose FE software Abaqus Standard to solve initial-boundary value problems. Considering the complexity of the system, the UEL development follows a stepwise manner by first solving the coupled hydraulic-mechanical (HM) and thermal-hydraulic-mechanical (THM) equations before moving on to the full THMC problem. Each implementation step consists of at least one verification test by comparing computed results with closed-form analytical solutions to ensure that the various coupling effects are correctly realized. To demonstrate the robustness of the algorithm and to validate the UEL, a three-dimensional case study is performed with reference to the in-situ heating test of ATLAS at Belgium in 1980s. A hypothetical radionuclide leakage event is then simulated by activating the chemical-concentration degree of freedom and prescribing a constant high concentration at the heater's surface. The model predicts a limited contaminated regime after six years considering both diffusion and advection effects on species transport.

finite element, nuclear waste storage, thermal pressurization, THMC coupling

## 1 | INTRODUCTION

Safe and permanent storage of spent nuclear fuel and other high-level radioactive wastes (HLWs) has been a pressing challenge given the ever-increasing amount of HLWs and the shortage of long-term storage facilities.<sup>1</sup> With multiple

approaches being discussed, an international consensus is that deep geological disposal is the preferred solution to the final management of HLW.<sup>2</sup> This technology is based on a combined natural and engineered multi-barrier system, where the host rock can efficiently retard the migration of hazardous radionuclides from the repository to the biosphere should a critical event happen. Because of the large time scale at concern, an important part of the design and performance assessment of underground HLW repositories is to predict the long-term evolution of the strongly coupled thermo-hydraulic-mechanical-chemical (THMC) processes in the clay buffers and the host rocks induced by material or energy release from the waste canisters. For example, the variation of pore pressure, water content, and elevated temperature could result in mechanical strain or even fractures in surrounding geomaterials.<sup>3</sup> In return, the skeleton deformation and fault displacement may alter the porosity and thus the permeability and diffusivity of the rock mass. Temperature change could be accelerated by fluid advection and chemical reaction. At the same time, heat transfer gives rise to thermal stresses and impacts mass transport of fluid as well as the reactive solute. Species migration is governed by concentration gradient but also influenced by fluid flow and thermal condition. Predicting the spatiotemporal evolution of such a complex environment near deep geological repositories requires reliable numerical models that can characterize all the relevant and highly nonlinear processes.<sup>4</sup>

To this end, considerable efforts have been devoted to developing solvers for the coupled nonlinear partial differential equations (PDEs) governing the THMC processes. Among the monolithic solvers, the OpenGeoSys (OGS) is an open-source numerical platform based on object-oriented finite element method (FEM), which is designed for multi-field problems of applications in geoscience and hydrology.<sup>5–7</sup> HYDROGEOCHEM is a suite of modules consisting of fluid flow, reactive biogeochemical transport, heat transfer and geomechanical displacement.<sup>8</sup> FEniCS is a popular and open-source computing framework that enables automated solution of PDEs with great flexibility and efficiency by a collection of FE-based libraries.<sup>9</sup> COMSOL Multiphysics is a commercial cross-platform finite element software and efficient solver for coupled PDEs, which has been successfully applied in THM(C) topics such as heat transfer in saturated soil,<sup>10</sup> methane hydrate<sup>11</sup> and CO<sub>2</sub> injection.<sup>12</sup> Apart from models that are solely based on FEM, the Los Alamos National Laboratory (LANL) has developed the Finite Element Heat and Mass Transfer (FEHM) code where the finite volume method (FVM) is utilized for flow and mass balance while FEM for stress equilibrium.<sup>13</sup> In addition, Feng et al.<sup>14</sup> proposed a method called the elasto-plastic cellular automaton (EPCA) which is inspired from the self-organization theory and has been used to simulate the fracturing of novaculite in a THMC environment.<sup>15</sup> Solution of coupled problems can also be achieved by combining different codes in a staggered manner, permitting flexibility in software development. This includes schemes that integrate reactive flow simulation with geomechanics codes such as TOUGHREACT-FLAC3D<sup>16–19</sup> and TReactMech,<sup>20,21</sup> or combining THM codes with geochemical simulator like MOOSE-REDBACK.<sup>22</sup> In general, sequential coupling approach has advantage on computational memory savings as well as implementation easiness. Whereas, solving coupled problems monolithically reduces communication and input/output (I/O) times compared to its staggered counterpart, which greatly benefits stability and avoids computational bottleneck.<sup>13,23</sup> It is worth to note that some of the aforementioned codes are open-source while others are proprietary, and their detailed numerical procedures are seldom published in scientific journal papers. This often make it challenging for users especially beginners to modify or implement new coupled theories to accommodate for different materials and engineering systems.

This study reports the authors' independent effort to develop a fully implicit monolithic finite element solution for THMC problems, with special emphasis on full disclosure of the implementation and verification details as well as the source code. Particularly, all codes and scripts presented here are made openly accessible via the [Supplementary materials](#) associated with this paper. We hope the details of the numerical procedure presented here can facilitate the numerical realization of other THMC or general multiphysical solvers. The FE software Abaqus Standard is chosen as the platform for our implementation considering its robust nonlinear solver that offers various implicit solution schemes as well as the automatic time-stepping capability. We start by outlining the general governing equations in Section 2. The thermoporoelasticity and the THM governing equations of Coussy<sup>24</sup> was adopted as the backbone of our THMC development. A user-defined element subroutine (UEL) is scripted in Section 3 based on the proposed governing equations. Considering the complexity of the system, the development starts by solving only the coupled hydromechanical equations, then extend to THM, and finally the complete THMC equations. Each implementation stage is verified by closed-form analytical solutions in Section 4. Finally, the UEL is put to simulate the in-situ heater test of ATLAS<sup>25</sup> in an underground research facility at Belgium (Section 5). The predicted THM responses of the host formation are evaluated against the measurement data from the experiment. A hypothetical leakage event is also simulated in the same FE model to examine the rate of contaminant migration through the host formation. The main conclusions of the study and possible future extensions are summarized in Section 6.

## 2 | GOVERNING EQUATIONS

This section develops the governing equations describing the multiphysical processes in porous geological media based on the conservation of mass, momentum, and energy. The possible THMC processes in various host rocks has been discussed in several review papers and reports.<sup>26</sup> To establish a set of tangible governing equations in this initial development, we emphasize the strong coupling between THM and their weak coupling with C. Specifically, the C component will focus on the transport of contaminant species driven by concentration gradient and advection associated with bulk fluid flow (i.e., THM → C). It is known that the presence of active chemical species can alter the THM properties of the solid skeleton through adsorption,<sup>27,28</sup> dissolution,<sup>29</sup> and pressure solution.<sup>30</sup> The system is also assumed to be fully saturated with no mass exchange between phases. This is likely to be true within the host rocks but not in the clay buffer where desaturation and vapor transportation may happen. These effects (i.e., C → THM) and phase changes may be included in future extensions of this basic framework. The main types of coupling considered in formulating the governing equations are summarized in Figure 1. Based on these considerations, the set of unknown field variables are identified, including skeleton displacement ( $\mathbf{u}$ ), fluid pressure ( $P_f$ ), temperature ( $T$ ), and contaminant molar concentration ( $C$ ).

### 2.1 | Balance equation of mass and contaminant mole

A continuous description of a porous medium requires the analysis at macroscopic scale in accordance with the hypothesis of continuity.<sup>24</sup> Given an arbitrary domain with volume  $\Omega_t$  and boundary  $\partial\Omega_t$ , the rate of change of quantity  $\xi$  (e.g., mass density, molar concentration) in the  $\alpha$  phase must be equal to the source/sink rate  $\dot{r}_\alpha$  subtracts the net outflux with respect to the observing window. The conservation of  $\xi$  can be written in the following form:

$$\frac{D^\alpha}{Dt} \int_{\Omega_t} \xi d\Omega_t = \int_{\Omega_t} \frac{\partial \xi}{\partial t} d\Omega_t + \int_{\partial\Omega_t} (\xi \mathbf{v}_\alpha) \cdot \mathbf{n} da = \int_{\Omega_t} \dot{r}_\alpha d\Omega_t \quad (1)$$

where

$$\frac{D^\alpha}{Dt} (\cdot) = \frac{\partial}{\partial t} (\cdot) + \mathbf{v}_\alpha \cdot \nabla_x (\cdot)$$

is the particle derivative with respect to the  $\alpha$  phase;  $\Omega_t$  is the domain volume;  $da$  is a unit domain boundary;  $\mathbf{v}_\alpha$  is the velocity of the  $\alpha$  phase;  $\nabla_x(\cdot)$  denotes gradient operation with respect to spatial coordinate;  $\alpha = s$  for solid and  $f$  for fluid in this development. As discussed previously, mass or species exchanges between phases are neglected in this study and thus  $\dot{r}_\alpha = 0$ . After applying divergence theorem, Equation (1) can be written in local form as:

$$\frac{\partial \xi}{\partial t} + \nabla_x \cdot (\xi \mathbf{v}_\alpha) = 0 \quad (2)$$

This equation is expressed in relation to a spatially fixed observation window. For FE implementation, governing equations often need to be expressed with respect to a window that moves along with the solid skeleton. Equation (2) can be thus re-written as

$$\frac{D^s}{Dt}(\xi) + \xi \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot [(\mathbf{v}_\alpha - \mathbf{v}_s) \xi] = 0 \quad (3)$$

Let  $\xi$  be the fluid mass per unit total volume ( $n\rho_f$ ), where  $n$  is the Eulerian porosity and  $\rho_f$  is the intrinsic density of the fluid. The fluid mass balance can be written based on Equation (3) as:

$$\rho_f \frac{D^s n}{Dt} + n \frac{D^s \rho_f}{Dt} + n \rho_f \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot \mathbf{q}_f = 0 \quad (4)$$

where  $\mathbf{q}_f$  is the relative flow vector of fluid mass:

$$\mathbf{q}_f = n \rho_f (\mathbf{v}_f - \mathbf{v}_s) \quad (5)$$

Similarly, the solid mass balance can be established by letting  $\xi$  be the solid mass per unit total volume  $(1-n)\rho_s$ :

$$-\rho_s \frac{D^s n}{Dt} + (1-n) \frac{D^s \rho_s}{Dt} + (1-n) \rho_s \nabla_x \cdot \mathbf{v}_s = 0 \quad (6)$$

where  $\rho_s$  is the intrinsic density of the solid. Set  $\xi$  as the contaminant molar concentration  $nC$  where  $C$  is amount of moles per unit fluid volume. The mole conservation equation for any contaminant species can be similarly written as:

$$\frac{D^s}{Dt}(nC) + nC \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot [(\mathbf{v}_C - \mathbf{v}_s) nC] = 0 \quad (7)$$

Define molar flux vector of contaminant relative to the bulk fluid flow

$$\mathbf{q}_C = nC (\mathbf{v}_C - \mathbf{v}_f) \quad (8)$$

Equation (7) can then be rewritten as

$$n \frac{D^s C}{Dt} + C \frac{D^s n}{Dt} + Cn \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot \left( \frac{C}{\rho_f} \mathbf{q}_f \right) + \nabla_x \cdot \mathbf{q}_C = 0 \quad (9)$$

## 2.2 | Mechanical equilibrium

The balance of linear momentum of porous domain  $\Omega_t$  can be written as

$$\frac{D^s}{Dt} \int_{\Omega_t} \rho_s (1-n) \mathbf{v}_s d\Omega_t + \frac{D^f}{Dt} \int_{\Omega_t} \rho_f n \mathbf{v}_f d\Omega_t = \int_{\Omega_t} \mathbf{b} d\Omega_t + \int_{\partial\Omega_t} \boldsymbol{\sigma} \cdot \mathbf{n} da \quad (10)$$

where  $\boldsymbol{\sigma}$  is the Cauchy stress tensor;  $\mathbf{b}$  is the body force per unit volume that only includes gravitational force in this model (i.e.  $\mathbf{b} = [n\rho_f + (1-n)\rho_s]\mathbf{g}$ ). Equation (10) can be further written in local form by considering Reynold transport theorem and mass balance for solid and fluid phases:

$$[\rho_s (1-n)] \boldsymbol{\gamma}_s + (\rho_f n) \boldsymbol{\gamma}_f = \nabla_x \cdot \boldsymbol{\sigma} + \mathbf{b} \quad (11)$$

where  $\boldsymbol{\gamma}_\alpha$  is the acceleration vector of phase  $\alpha = s$  or  $f$ . Under quasi-static condition which is of the current interest, all the inertia terms can be neglected and the equilibrium equation becomes

$$\nabla_x \cdot \boldsymbol{\sigma} + \mathbf{b} = 0 \quad (12)$$

### 2.3 | Balance equation of internal energy

For fine-grained porous media, local thermal equilibrium is a reasonable assumption considering the rapid conduction between the fluid and the solid phases.<sup>12</sup> This means a single value  $T$  can be used to represent the absolute temperature of all phases in the representative element volume (REV). Neglecting the mechanical work, the balance of internal energy of the system can be written as

$$\begin{aligned} \frac{D^s}{Dt} \int_{\Omega_t} [(1-n)\rho_s c_s T + n\rho_f c_f T] dV \\ = - \int_{\partial\Omega_t} n\rho_f c_f T (\mathbf{v}_f - \mathbf{v}_s) \cdot \mathbf{n} dA - \int_{\partial\Omega_t} \mathbf{q}_T \cdot \mathbf{n} dA + \int_{\Omega_t} \dot{r}_T dV \end{aligned} \quad (13)$$

where  $c_\alpha$  is the specific heat of phase  $\alpha$ ; the first term on the right-hand side (RHS) accounts for the advective energy flux due to fluid escaping on the domain boundary;  $\mathbf{q}_T$  is the rate of heat flux due to thermal conduction. Applying the Reynold transport theorem and divergence theorem and setting  $\dot{r}_T = 0$ , the local form of energy balance can be written as:

$$\frac{\partial [(1-n)\rho_s c_s T + n\rho_f c_f T]}{\partial t} + \nabla_x \cdot (1-n)\rho_s c_s T \mathbf{v}_s + \nabla_x \cdot n\rho_f c_f T \mathbf{v}_f + \nabla_x \cdot \mathbf{q}_T = 0 \quad (14)$$

or

$$\frac{D^s}{Dt} [(1-n)\rho_s c_s T + n\rho_f c_f T] + [(1-n)\rho_s c_s T + n\rho_f c_f T] \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot c_f T \mathbf{q}_f + \nabla_x \cdot \mathbf{q}_T = 0 \quad (15)$$

Assuming  $c_s$  and  $c_f$  are constant, Equation (15) can be finally expanded as:

$$\begin{aligned} [(1-n)\rho_s c_s + n\rho_f c_f] \frac{D^s T}{Dt} \\ + T \left[ c_s \rho_s \frac{D^s (1-n)}{Dt} + c_s (1-n) \frac{D^s \rho_s}{Dt} + c_f \rho_f \frac{D^s n}{Dt} + c_f n \frac{D^s \rho_f}{Dt} \right] \\ + [(1-n)\rho_s c_s T + n\rho_f c_f T] \nabla_x \cdot \mathbf{v}_s + \nabla_x \cdot c_f T \mathbf{q}_f + \nabla_x \cdot \mathbf{q}_T = 0 \end{aligned} \quad (16)$$

### 2.4 | Constitutive relation and conduction laws

At material level, we need to specify (1) a constitutive relation to describe the mechanical behavior of the REV under stress, fluid pressure, and temperature variation, and (2) a set of conduction laws to describe fluid flow, contaminant transport and heat transfer under their driving gradients. The material model shall be implemented in a hierarchical way such that different types of constitutive laws which may be nonlinear, inelastic, and anisotropic can be easily accommodated. This will be discussed in the next section. To have a starting point, we choose the thermoporoelastic theory by Coussy<sup>24</sup> as the constitutive model. The expression of this model in terms of infinitesimal strain is given by:

$$\sigma_{ij} - \sigma_{ij,0} = C_{ijkl} \varepsilon_{kl} - b_{ij} (P_f - P_{f,0}) - C_{ijkl} \alpha_{kl} (T - T_0) \quad (17)$$

$$\phi - \phi_0 = b_{ij} \varepsilon_{ij} + \frac{P_f - P_{f,0}}{N} - 3\alpha_\phi (T - T_0) \quad (18)$$

where

$$\varepsilon = \frac{1}{2} (\nabla \mathbf{u} + \nabla \mathbf{u}^T) \quad (19)$$

is the infinitesimal strain tensor;  $\phi$  the Lagrangian porosity;  $b_{ij}$  the Biot's coefficient;  $\alpha_{kl}$  the thermal expansion coefficient of the solid;  $N$  the Biot's tangent modulus linking pressure and porosity changes;  $3\alpha_\phi$  the volumetric thermal dilation coefficient related with porosity;  $C_{ijkl}$  the stiffness matrix of the skeleton;  $\sigma_{ij,0}$ ,  $P_{f,0}$ ,  $T_0$  and  $\phi_0$  characterize the reference initial state of the specimen. Equations (17) and (18) can be further simplified by assuming linear isotropic elastic response and

isotropic thermal expansion coefficient. Additionally, a conversion between porosity  $\phi$  to  $n$  is necessary to maintain consistency with the field equations. Under infinitesimal strain condition, we have  $\phi = Jn \approx (1 + \varepsilon_v)n$  according to Coussy.<sup>24</sup> The relation between the increments of the two porosity measures can be derived as:

$$d\phi \approx dn + \varepsilon_v dn + n d\varepsilon_v \approx dn + n d\varepsilon_v \quad (20)$$

where  $\varepsilon_v dn$  is neglected because it is a second-order infinitesimal term. Considering the above, Equations (17) and (18) can be simplified to:

$$\sigma_{ij} - \sigma_{ij,0} = \left( K - \frac{2}{3}G \right) \varepsilon_v \delta_{ij} + 2G\varepsilon_{ij} - b(P_f - P_{f,0})\delta_{ij} - 3\alpha K(T - T_0)\delta_{ij} \quad (21)$$

$$n - n_0 = (b - n)\varepsilon_v + \frac{P_f - P_{f,0}}{N} - 3\alpha_\phi(T - T_0) \quad (22)$$

where  $K$  is the bulk modulus and  $G$  is the shear modulus;  $b$  and  $\alpha$  the isotropic Biot's coefficient and thermal expansion coefficient, respectively;  $\varepsilon_v = \varepsilon_{ii}$  the volumetric strain;  $\delta_{ij}$  the Kronecker delta.

Equations (21) and (22) can be rewritten in incremental matrix form for numerical implementation:

$$\begin{bmatrix} d\sigma_{11} \\ d\sigma_{22} \\ d\sigma_{33} \\ d\sigma_{23} \\ d\sigma_{13} \\ d\sigma_{12} \\ dn \end{bmatrix} = \begin{bmatrix} K + \frac{4}{3}G & K - \frac{2}{3}G & K - \frac{2}{3}G & 0 & 0 & 0 & -b & -3\alpha K \\ K - \frac{2}{3}G & K + \frac{4}{3}G & K - \frac{2}{3}G & 0 & 0 & 0 & -b & -3\alpha K \\ K - \frac{2}{3}G & K - \frac{2}{3}G & K + \frac{4}{3}G & 0 & 0 & 0 & -b & -3\alpha K \\ 0 & 0 & 0 & 2G & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2G & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 2G & 0 & 0 \\ b - n & b - n & b - n & 0 & 0 & 0 & \frac{1}{N} & -3\alpha_\phi \end{bmatrix} \begin{bmatrix} d\varepsilon_{11} \\ d\varepsilon_{22} \\ d\varepsilon_{33} \\ d\varepsilon_{23} \\ d\varepsilon_{13} \\ d\varepsilon_{12} \\ dP_f \\ dT \end{bmatrix} \quad (23)$$

Regarding the conduction laws, it is possible to write a general linear conduction law:

$$\begin{bmatrix} \mathbf{q}_f \\ \mathbf{q}_T \\ \mathbf{q}_C \end{bmatrix} = - \begin{bmatrix} \mathbf{k}_{HH} & \mathbf{k}_{HT} & \mathbf{k}_{HC} \\ \mathbf{k}_{TH} & \mathbf{k}_{TT} & \mathbf{k}_{TC} \\ \mathbf{k}_{CH} & \mathbf{k}_{CT} & \mathbf{k}_{CC} \end{bmatrix} \begin{bmatrix} \nabla P_f - \rho_f \mathbf{g} \\ \nabla T \\ \nabla C \end{bmatrix} \quad (24)$$

The simplest conduction law controls fluid flow is the Darcy's law which states a linear relation between  $\mathbf{q}_f$  and  $\nabla P_f$ :

$$\mathbf{q}_f = -\frac{\rho_f k}{\mu} (\nabla_x P_f - \rho_f \mathbf{g}) \quad (25)$$

where  $k$  is the permeability and  $\mu$  is the dynamic viscosity of the fluid. Similarly, the contaminant diffusion and heat conduction are classically described by the Fick's and the Fourier's law, respectively:

$$\mathbf{q}_C = -D_C \nabla_x C \quad (26)$$

$$\mathbf{q}_T = -\kappa \nabla_x T \quad (27)$$

where  $D_C$  is the diffusivity of contaminant species;  $\kappa$  is the thermal diffusivity. The diffusion coefficients  $k$ ,  $D_C$  and  $\kappa$  are scalars for isotropic solid, which is what we have assumed here. Neglecting the coupling terms, the simplest form of

**TABLE 1** Governing equations<sup>a</sup> for the coupled THMC processes.

Physics	Unknowns	Governing equations
M (mechanical)	$\mathbf{u}$	$\nabla \cdot \boldsymbol{\sigma} + \mathbf{b} = 0$ with $\mathbf{b} = [n\rho_f + (1-n)\rho_s]\mathbf{g}$
H (hydraulic)	$P_f$	$\rho_f \dot{n} + n(\frac{\rho_f}{K_f} \dot{P}_f - 3\rho_f \alpha_f \dot{T}) + n\rho_f \dot{\varepsilon}_v + \nabla \cdot \mathbf{q}_f = 0$
C (Chemical)	$C$	$n\dot{C} + C\dot{n} + Cn\dot{\varepsilon}_v + \nabla \cdot (\frac{C}{\rho_f} \mathbf{q}_f) + \nabla \cdot \mathbf{q}_C = 0$
T (Thermal)	$T$	$[(1-n)\rho_s c_s + n\rho_f c_f] \dot{T} +$ $T \left\{ -c_s \rho_s \left[ (1-b) \dot{\varepsilon}_v - \frac{\dot{P}_f}{N} + 3\alpha_\phi \dot{T} \right] \right.$ $\left. + (c_f \rho_f - c_s \rho_s) \dot{n} + c_f n \left( \dot{P}_f \frac{\rho_f}{K_f} - 3\rho_f \alpha_f \dot{T} \right) \right\}$ $+ [(1-n)\rho_s c_s T + n\rho_f c_f T] \dot{\varepsilon}_v + \nabla \cdot (c_f T \mathbf{q}_f) + \nabla \cdot \mathbf{q}_T = 0$

<sup>a</sup>Note that  $\boldsymbol{\sigma}$ ,  $n$ ,  $\varepsilon_v$ ,  $\mathbf{q}_f$ ,  $\mathbf{q}_C$ ,  $\mathbf{q}_T$  are intermediate variables. They can be expressed in terms of the unknowns  $[\mathbf{u}, P_f, C, T]$  via constitutive relation Equation (23), strain-displacement relation Equation (19), and conduction laws Equation (28).

Equation (24) can be written by collecting Equations (25)–(27):

$$\begin{bmatrix} \mathbf{q}_f \\ \mathbf{q}_T \\ \mathbf{q}_C \end{bmatrix} = - \begin{bmatrix} \rho_f k / \mu & 0 & 0 \\ 0 & \kappa & 0 \\ 0 & 0 & D_C \end{bmatrix} \begin{bmatrix} \nabla_x P_f - \rho_f \mathbf{g} \\ \nabla_x T \\ \nabla_x C \end{bmatrix} \quad (28)$$

## 2.5 | Equation of state

Finally, the compressibility of the fluid and the solid phases needs to be defined to close the system. Assuming the intrinsic fluid density is a function of pore pressure  $P_f$  and temperature  $T$ , the equation of state for the fluid phase can be written as

$$d\rho_f = \frac{\partial \rho_f}{\partial P_f} dP_f + \frac{\partial \rho_f}{\partial T} dT = \frac{\rho_f}{K_f} dP_f - 3\rho_f \alpha_f dT \quad (29)$$

where  $3\alpha_f$  is the coefficient of volumetric thermal expansion of the fluid;  $K_f$  is fluid bulk modulus. For the solid phase, combining solid mass balance Equation (6) and the porosity evolution law Equation (22) gives

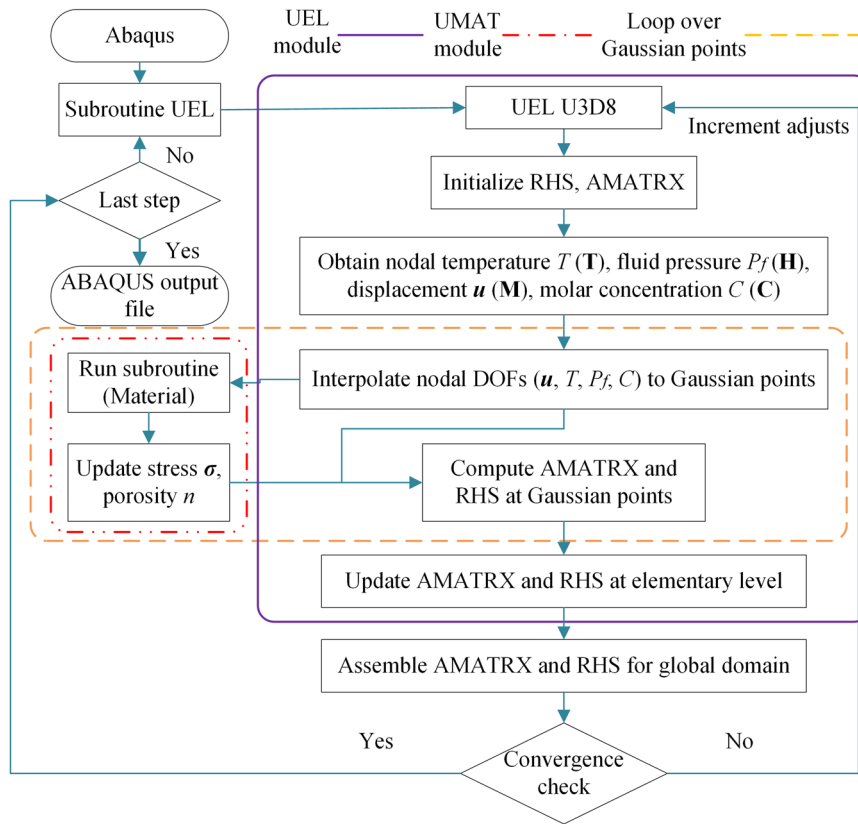

$$d\rho_s = \frac{-\rho_s}{1-n} \left[ (1-b) d\varepsilon_v - \frac{dP_f}{N} + 3\alpha_\phi dT \right] \quad (30)$$

After supplying Equations (29) and (30), the final THMC governing equations are derived and summarized in Table 1. For conciseness, the operator  $D^s \xi / Dt$  is replaced by superposed dot  $\dot{\xi}$ ; the spatial gradient  $\nabla_x$  is replaced by  $\nabla$ ;  $\nabla \cdot \mathbf{v}_s$  is essentially the volumetric strain rate  $\dot{\varepsilon}_v$ . The key assumptions behind the equations in Table 1 are: (1) The host rock under consideration is fully saturated, linear elastic, with compressible constituents undergoing small deformations, whereas plasticity, damage, or partial saturation of the rock are not considered; (2) The effect of stress and temperature on the transport coefficients (e.g., permeability, diffusivity) are neglected; (3) The effects of fluid chemistry on the THM properties of the host rock through processes such as adsorption, dissolution, and pressure solution (i.e.,  $C \rightarrow \text{THM}$ ) are omitted. The system is to be solved by the finite element method, complemented by constitutive relation Equation (23) and conduction law Equation (28).

## 3 | FINITE ELEMENT IMPLEMENTATION

In this section, the governing equations are spatially and temporally discretized and solved under an iterative scheme through the user-define element (UEL) subroutine combined with Abaqus Standard. It should be acknowledged that this

**FIGURE 2** Workflow of THMC modeling via Abaqus + UEL.

development mainly follows the UEL implementation of a coupled diffusion-deformation theory for elastomeric gels by Chester et al.<sup>31</sup>

### 3.1 | The structure of UEL

The UEL subroutine permits user-defined variational form of the elemental Jacobian (or tangent stiffness) matrix (AMATRX) and the residual vector (RHS) in solving customized equation systems. We choose to use a three-dimensional trilinear hexahedron element (U3D8) with 6 degrees of freedom (DOFs) which are respectively  $u_x$ ,  $u_y$ ,  $u_z$ ,  $P_f$ ,  $C$  and  $T$  for each node (See Appendix, Figure A). Admittedly, this type of element do not satisfy the Ladyzhenskaya–Babuska–Brezzi (LBB) condition<sup>32,33</sup> and can give unphysical oscillation in the results. Multiple techniques have been developed to avoid such spurious pressure mode.<sup>23,34,35</sup> Considering these oscillations are short-lived and do not impair the equilibrium or the long-term solution of interest to this study, we opt for the basic low-order element type in this first-stage development. Similar approach is also adopted in other coupled deformation-diffusion UEL codes.<sup>31</sup>

The proposed UEL is hierarchically structured so that it does not contain any constitutive information of the material. Instead, the UEL will call a separate *Material* subroutine at material integration points to retrieve the constitutive relations. The advantage of doing so is to have the versatility to switch to advanced material models should the nonlinear, inelastic, and anisotropic responses of different rock formations be incorporated in the future. The workflow is sketched in Figure 2. At the starting point, nodal coordinates (COORDS), estimated DOFs for next step (U), and material parameters defined in an input file (PROPS) are passed from Abaqus to the UEL. After interpolation from nodal values, this information computes the RHS and AMATRX at each Gauss point, which will be upscaled to the element level through Gauss quadrature. In addition, all solution dependent variables (SVARS) are updated and stored at the end of each iteration.<sup>36</sup> Whenever the UEL is called, it returns the elemental RHS and AMATRX which will be later assembled for the global Newton-Raphson iteration in the Abaqus Standard solver. If the global RHS meets the desired tolerance, we say the system reaches convergence and the PDEs are numerically solved.

Visualization of the computed results is not straightforward as Abaqus cannot automatically extrapolate variables from Gauss points to nodes for user-customized shape functions. This can be addressed by coding a python script that accesses the output database and translates the data format to be compatible with other third-party post-processing software.<sup>37</sup> Here a convenient approach that only involves Abaqus CAE is adopted: each user-defined element is overlaid by an Abaqus built-in element (also called the dummy element) which has the identical shape function as the UEL. The material-point quantities computed from the UEL are passed to the dummy element via subroutine UVARM, which can then be understood and visualized by Abaqus CAE. To avoid interferences with the FE computations, all dummy elements must be assigned with near-zero stiffness and T/H/C conductivity coefficients.

### 3.2 | Boundary and initial conditions

The definition of boundary and initial conditions are required to complete the formulation of IBVP given a time interval  $t \in [0, T]$ . For a domain  $\Omega$  with boundary  $\Gamma = \partial\Omega$ , let  $\Gamma_\beta^D$  and  $\Gamma_\beta^N$  be a pair of complementary subsurface where the Dirichlet and Neumann boundary conditions are prescribed respectively for the  $\beta$  field ( $\beta = M, H, C, T$ ), following the relation that  $\Gamma = \Gamma_\beta^D \cup \Gamma_\beta^N$  and  $\Gamma_\beta^D \cap \Gamma_\beta^N = \emptyset$ . Therefore, the formal statement of initial and boundary conditions for the fully coupled THMC system are as follows:

$$\text{M(mechanical)} : \begin{cases} \mathbf{u}(\mathbf{x}, 0) = \mathbf{u}_0(\mathbf{x}) \\ \mathbf{u} = \bar{\mathbf{u}} \quad \forall \mathbf{x} \in \Gamma_M^D \\ \boldsymbol{\sigma} \mathbf{n} = \bar{\mathbf{t}} \quad \forall \mathbf{x} \in \Gamma_M^N \end{cases} \quad (31)$$

$$\text{H(hydraulic)} : \begin{cases} P_f(\mathbf{x}, 0) = P_{f,0}(\mathbf{x}) \text{ and } n(\mathbf{x}, 0) = n_0(\mathbf{x}) \\ P_f = \bar{P}_f \quad \forall \mathbf{x} \in \Gamma_H^D \\ \mathbf{q}_f \mathbf{n} = \bar{q}_f \quad \forall \mathbf{x} \in \Gamma_H^N \end{cases} \quad (32)$$

$$\text{C(chemical)} : \begin{cases} C(\mathbf{x}, 0) = C_0(\mathbf{x}) \\ C = \bar{C} \quad \forall \mathbf{x} \in \Gamma_C^D \\ \mathbf{q}_C \mathbf{n} = \bar{q}_C \quad \forall \mathbf{x} \in \Gamma_C^N \\ C \mathbf{q}_f \mathbf{n} = \bar{q}_{C,f} \quad \forall \mathbf{x} \in \Gamma_{C,H}^N \end{cases} \quad (33)$$

$$\text{T(thermal)} : \begin{cases} T(\mathbf{x}, 0) = T_0(\mathbf{x}) \\ T = \bar{T} \quad \forall \mathbf{x} \in \Gamma_T^D \\ \mathbf{q}_T \mathbf{n} = \bar{q}_T \quad \forall \mathbf{x} \in \Gamma_T^N \\ c_f T \mathbf{q}_f \mathbf{n} = \bar{q}_{T,f} \quad \forall \mathbf{x} \in \Gamma_{T,H}^N \end{cases} \quad (34)$$

### 3.3 | Weak form and discretization

We shall now construct the weak form of the THMC problem by multiplying the residual with a set weight functions  $\mathbf{w}_1, \mathbf{w}_2, \mathbf{w}_3, \mathbf{w}_4$  and integrating over the whole domain for solving the unknowns  $\mathbf{u}, P_f, C, T$ , respectively. In terms of integral forms for weighted residuals, trial functions for solution approximation must be selected from a Sobolev space  $H^m$  (of order  $m$ ) with the embedded Dirichlet boundary conditions. Likewise, weight functions  $(\mathbf{w}_1, \mathbf{w}_2, \mathbf{w}_3, \mathbf{w}_4)$  are selected from Sobolev space with the same continuity and differentiability requirements but will vanish on the Dirichlet boundaries.

Combining those derivation of integrating products, definition for weight and trial functions, and Neumann boundary conditions defined in Equations (31)–(34), the weak forms are stated as follows:

$$\mathbf{M} : \left\{ \begin{array}{l} \int_{\Omega} \nabla_s^T \mathbf{w}_1 \boldsymbol{\sigma} d\Omega = \mathbf{w}_1 \tilde{\mathbf{t}} + \int_{\Omega} \mathbf{w}_1 [n\rho_f + (1-n)\rho_s] \mathbf{g} d\Omega \\ \mathbf{u} \in H^1(\Omega) : \mathbf{u} = \tilde{\mathbf{u}} \quad \forall \mathbf{x} \in \Gamma_M^D \\ \mathbf{w}_1 \in H^1(\Omega) : \mathbf{w}_1 = 0 \quad \forall \mathbf{x} \in \Gamma_M^D \end{array} \right\} \quad (35)$$

$$\mathbf{H} : \left\{ \begin{array}{l} \int_{\Omega} w_2 \rho_f \dot{n} d\Omega + \int_{\Omega} w_2 n (\rho_f \dot{P}_f / K^f - 3\rho_f \alpha_f \dot{T}) d\Omega \\ + w_2 n \rho_f \dot{\epsilon}_v d\Omega + w_2 \tilde{q}_f^N - \int_{\Omega} \mathbf{q}_f \cdot \nabla w_2 d\Omega = 0 \\ P_f \in H^1(\Omega) : P_f = \tilde{P}_f \quad \forall \mathbf{x} \in \Gamma_H^D \\ w_2 \in H^1(\Omega) : w_2 = 0 \quad \forall \mathbf{x} \in \Gamma_H^D \end{array} \right\} \quad (36)$$

$$\mathbf{C} : \left\{ \begin{array}{l} \int_{\Omega} w_3 n \dot{C} d\Omega + \int_{\Omega} w_3 C \dot{n} d\Omega + \int_{\Omega} w_3 (Cn) \dot{\epsilon}_v d\Omega \\ + w_3 \frac{\tilde{q}_{C,f}^N}{\rho_f} - \int_{\Omega} \left( \frac{C \mathbf{q}_f}{\rho_f} \right) \cdot \nabla w_3 d\Omega + w_3 \tilde{q}_C^N - \int_{\Omega} \mathbf{q}_C \cdot \nabla w_3 d\Omega = 0 \\ C \in H^1(\Omega) : C = \tilde{C} \quad \forall \mathbf{x} \in \Gamma_C^D \\ w_3 \in H^1(\Omega) : w_3 = 0 \quad \forall \mathbf{x} \in \Gamma_C^D \end{array} \right\} \quad (37)$$

$$\mathbf{T} : \left\{ \begin{array}{l} \int_{\Omega} w_4 \left\{ \begin{array}{l} [(1-n)\rho_s c_s + n\rho_f c_f] \dot{T} - T c_s \rho_s \left[ (1-b)\dot{\epsilon}_v - \frac{\dot{P}_f}{N} + 3\alpha_f \dot{T} \right] \\ + T (c_f \rho_f - c_s \rho_s) \dot{n} + T c_f n \rho_f \left( \frac{\dot{P}_f}{K^f} - 3\alpha_f \dot{T} \right) \\ + [(1-n)\rho_s c_s T + n\rho_f c_f T] \dot{\epsilon}_v \end{array} \right\} d\Omega \\ + w_4 c_f T \tilde{q}_{T,f}^N - \int_{\Omega} c_f T \mathbf{q}_f \cdot \nabla w_4 d\Omega + w_4 \tilde{q}_T^N - \int_{\Omega} \mathbf{q}_T \cdot \nabla w_4 d\Omega = 0 \\ T \in H^1(\Omega) : T = \tilde{T} \quad \forall \mathbf{x} \in \Gamma_T^D \\ w_4 \in H^1(\Omega) : w_4 = 0 \quad \forall \mathbf{x} \in \Gamma_T^D \end{array} \right\} \quad (38)$$

The finite element formulation is established by applying the Bubnov-Galerkin method, where the solution can be approximated by using the identical shape function  $\mathbf{N}$  for trial and weight functions, namely:

M: with  $\mathbf{u} = \mathbf{N}\tilde{\mathbf{u}}$  and  $\mathbf{w}_1 = \mathbf{N}\tilde{\mathbf{w}}_1$

$$\int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma}(\mathbf{u}) d\Omega - \mathbf{N}^T \tilde{\mathbf{t}} - \int_{\Omega} \mathbf{N}^T [n\rho_f + (1-n)\rho_s] \mathbf{g} d\Omega = 0 \quad (39)$$

H: with  $P_f = \mathbf{N}\tilde{P}_f$  and  $w_2 = \mathbf{N}\tilde{w}_2$

$$\begin{aligned} & \int_{\Omega} \mathbf{N}^T \rho_f \dot{n} d\Omega + \int_{\Omega} \mathbf{N}^T n (\rho_f / K^f \dot{P}_f - 3\rho_f \alpha_f \dot{T}) d\Omega \\ & + \int_{\Omega} \mathbf{N}^T n \rho_f \dot{\epsilon}_v d\Omega + \mathbf{N}^T \tilde{q}_f^N - \int_{\Omega} (\nabla \mathbf{N})^T \mathbf{q}_f d\Omega = 0 \end{aligned} \quad (40)$$

C: with  $C = \widetilde{\mathbf{N}}\mathbf{C}$  and  $w_3 = \widetilde{\mathbf{N}}\mathbf{w}_3$

$$\begin{aligned} & \mathbf{N}^T n \dot{C} d\Omega + \int_{\Omega} \mathbf{N}^T C \dot{n} d\Omega + \int_{\Omega} \mathbf{N}^T (Cn) \dot{\epsilon}_v d\Omega \\ & + \mathbf{N}^T \widetilde{q}_{C,f}^N / \rho_f + \int_{\Omega} \mathbf{N}^T C / \rho_f \nabla \mathbf{q}_f d\Omega + \mathbf{N}^T \widetilde{q}_C^N - \int_{\Omega} \mathbf{q}_C \cdot \nabla \mathbf{N} d\Omega = 0 \end{aligned} \quad (41)$$

T: with  $T = \widetilde{\mathbf{N}}\mathbf{T}$  and  $w_4 = \widetilde{\mathbf{N}}\mathbf{w}_4$

$$\begin{aligned} & \int_{\Omega} \mathbf{N}^T [(1-n)\rho_s c_s + n\rho_f c_f] \dot{T} d\Omega - \int_{\Omega} \mathbf{N}^T T c_s \rho_s [(1-b)\dot{\epsilon}_v - \dot{P}_f / N + 3\alpha_\phi \dot{T}] d\Omega \\ & + \int_{\Omega} \mathbf{N}^T T (c_f \rho_f - c_s \rho_s) \dot{n} d\Omega + \int_{\Omega} \mathbf{N}^T T c_f n \rho_f (\dot{P}_f / K^f - 3\alpha_\phi \dot{T}) d\Omega \\ & + \int_{\Omega} \mathbf{N}^T [(1-n)\rho_s c_s + n\rho_f c_f] T \dot{\epsilon}_v d\Omega \\ & + \mathbf{N}^T c_f \widetilde{q}_{T,f}^N - \int_{\Omega} c_f T \mathbf{q}_f \cdot \nabla \mathbf{N} d\Omega + \mathbf{N}^T \widetilde{q}_T^N - \int_{\Omega} \mathbf{q}_T \cdot \nabla \mathbf{N} d\Omega = 0 \end{aligned} \quad (42)$$

where

$$\mathbf{B} = \nabla_s \mathbf{N} = \begin{bmatrix} \frac{\partial N_1}{\partial x} & 0 & 0 & \frac{\partial N_2}{\partial x} & 0 & 0 & \dots & \frac{\partial N_n}{\partial x} & 0 & 0 \\ 0 & \frac{\partial N_1}{\partial y} & 0 & 0 & \frac{\partial N_2}{\partial y} & 0 & \dots & 0 & \frac{\partial N_n}{\partial y} & 0 \\ 0 & 0 & \frac{\partial N_1}{\partial z} & 0 & 0 & \frac{\partial N_2}{\partial z} & \dots & 0 & 0 & \frac{\partial N_n}{\partial z} \\ 0 & \frac{\partial N_1}{\partial z} & \frac{\partial N_1}{\partial y} & 0 & \frac{\partial N_2}{\partial z} & \frac{\partial N_2}{\partial y} & \dots & 0 & \frac{\partial N_n}{\partial z} & \frac{\partial N_n}{\partial y} \\ \frac{\partial N_1}{\partial z} & 0 & \frac{\partial N_1}{\partial x} & \frac{\partial N_2}{\partial z} & 0 & \frac{\partial N_1}{\partial x} & \dots & \frac{\partial N_n}{\partial z} & 0 & \frac{\partial N_n}{\partial x} \\ \frac{\partial N_1}{\partial y} & \frac{\partial N_1}{\partial x} & 0 & \frac{\partial N_2}{\partial y} & \frac{\partial N_1}{\partial x} & 0 & \dots & \frac{\partial N_n}{\partial y} & \frac{\partial N_n}{\partial x} & 0 \end{bmatrix} \quad (43)$$

More details about the element type and expanded shape function are presented in Appendix A.

### 3.4 | UEL implementation

During each iteration attempt, the elemental Jacobian  $\mathbf{K} = \text{AMATRX}$  and the residual  $\mathbf{R} = \text{RHS}$  must be evaluated to solve all nodal unknowns  $\delta \mathbf{x}$  via:

$$\mathbf{K} \delta \mathbf{x} = \mathbf{R}$$

or

$$\underbrace{\begin{bmatrix} \underbrace{\mathbf{K}_{uu}^{t+\Delta t}}_{3n_e \times 3n_e} & \underbrace{\mathbf{K}_{uP}^{t+\Delta t}}_{3n_e \times n_e} & \underbrace{\mathbf{K}_{uC}^{t+\Delta t}}_{3n_e \times n_e} & \underbrace{\mathbf{K}_{uT}^{t+\Delta t}}_{3n_e \times n_e} \\ \underbrace{\mathbf{K}_{Pu}^{t+\Delta t}}_{n_e \times 3n_e} & \underbrace{\mathbf{K}_{PP}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{PC}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{PT}^{t+\Delta t}}_{n_e \times n_e} \\ \underbrace{\mathbf{K}_{Cu}^{t+\Delta t}}_{n_e \times 3n_e} & \underbrace{\mathbf{K}_{CP}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{CC}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{CT}^{t+\Delta t}}_{n_e \times n_e} \\ \underbrace{\mathbf{K}_{Tu}^{t+\Delta t}}_{n_e \times 3n_e} & \underbrace{\mathbf{K}_{TP}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{TC}^{t+\Delta t}}_{n_e \times n_e} & \underbrace{\mathbf{K}_{TT}^{t+\Delta t}}_{n_e \times n_e} \end{bmatrix}}_{\text{AMATRX}} \underbrace{\begin{bmatrix} \underbrace{\delta \mathbf{u}}_{3n_e \times 1} \\ \underbrace{\delta P_f}_{n_e \times 1} \\ \underbrace{\delta C}_{n_e \times 1} \\ \underbrace{\delta T}_{n_e \times 1} \end{bmatrix}}_{\mathbf{RHS}} = \underbrace{\begin{bmatrix} \underbrace{-\mathbf{R}_M^{t+\Delta t}}_{3n_e \times 1} \\ \underbrace{-R_H^{t+\Delta t}}_{n_e \times 1} \\ \underbrace{-R_C^{t+\Delta t}}_{n_e \times 1} \\ \underbrace{-R_T^{t+\Delta t}}_{n_e \times 1} \end{bmatrix}}_{\text{RHS}} \quad (44)$$

where  $n_e$  is the number of nodes which equals to 8 for the current element type U3D8. According to Equations (39)–(42), the residual  $\mathbf{R}$  at  $t + \Delta t$  step is given below:

$$\mathbf{R}_M^{t+\Delta t} = - \int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma}^{t+\Delta t} d\Omega - \mathbf{N}^T \tilde{\mathbf{t}} + \int_{\Omega} \mathbf{N}^T [n^{t+\Delta t} \rho_f + (1 - n^{t+\Delta t}) \rho_s] \mathbf{g} d\Omega \quad (45)$$

$$\begin{aligned} R_H^{t+\Delta t} = & - \int_{\Omega} \mathbf{N}^T \rho_f \dot{n} d\Omega - \int_{\Omega} \mathbf{N}^T n (\rho_f \dot{P}_f / K^f - 3\rho_f \alpha_f \dot{T}) d\Omega \\ & - \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T n^{t+\Delta t} \rho_f \dot{\epsilon}_v d\Omega - \int_{\partial\Omega_f^k} \mathbf{N}^T \tilde{\mathbf{q}}_f^k dA + \int_{\Omega} (\nabla \mathbf{N})^T \mathbf{q}_f^{t+\Delta t} d\Omega \end{aligned} \quad (46)$$

$$\begin{aligned} R_C^{t+\Delta t} = & - \int_{\Omega} \mathbf{N}^T n^{t+\Delta t} \dot{C} d\Omega - \int_{\Omega} \mathbf{N}^T C^{t+\Delta t} \dot{n} d\Omega - \int_{\Omega} \mathbf{N}^T (C^{t+\Delta t} n^{t+\Delta t}) \dot{\epsilon}_v d\Omega \\ & - \mathbf{N}^T \tilde{\mathbf{q}}_{C,f}^{N,t+\Delta t} / \rho_f + \int_{\Omega} (C^{t+\Delta t} \mathbf{q}_f^{t+\Delta t} / \rho_f) \cdot \nabla \mathbf{N} d\Omega - \mathbf{N}^T \tilde{\mathbf{q}}_C^{N,t+\Delta t} + \int_{\Omega} \mathbf{q}_C^{t+\Delta t} \cdot \nabla \mathbf{N} d\Omega \end{aligned} \quad (47)$$

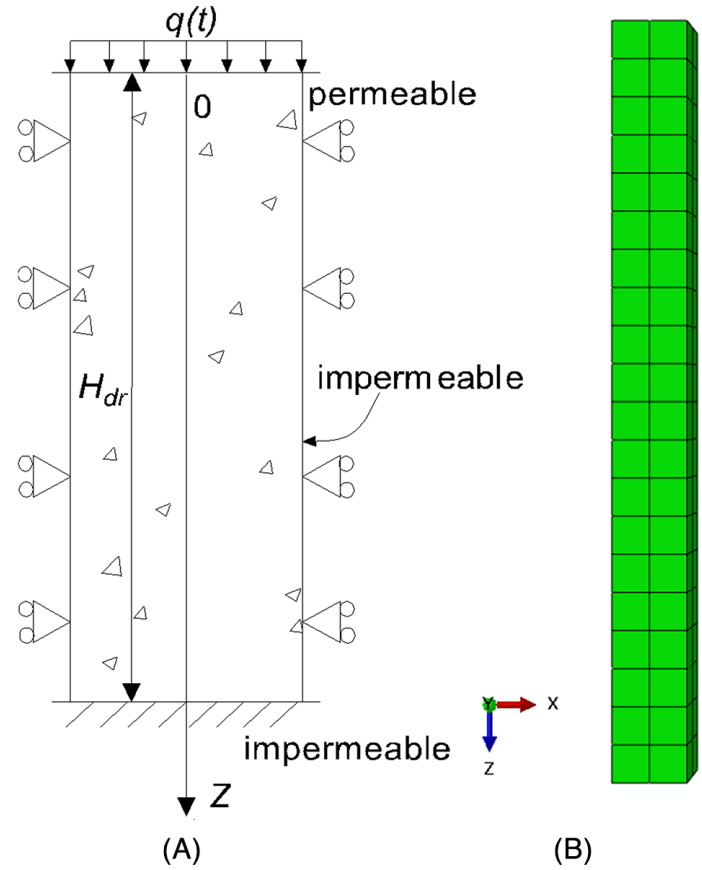

$$\begin{aligned} R_T^{t+\Delta t} = & - \int_{\Omega} \mathbf{N}^T [(1 - n^{t+\Delta t}) \rho_s c_s + n^{t+\Delta t} \rho_f c_f] \dot{T} d\Omega \\ & + \int_{\Omega} \mathbf{N}^T T^{t+\Delta t} c_s \rho_s [(1 - b) \dot{\epsilon}_v - \dot{P}_f^{t+\Delta t} / N + 3\alpha_\phi \dot{T}] d\Omega \\ & - \int_{\Omega} \mathbf{N}^T T^{t+\Delta t} (c_f \rho_f - c_s \rho_s) \dot{n} d\Omega - \int_{\Omega} \mathbf{N}^T T^{t+\Delta t} c_f n^{t+\Delta t} \rho_f (\dot{P}_f / K^f - 3\alpha_f \dot{T}) d\Omega \\ & - \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T [(1 - n^{t+\Delta t}) \rho_s c_s + n^{t+\Delta t} \rho_f c_f] T^{t+\Delta t} \dot{\epsilon}_v d\Omega - \mathbf{N}^T c_f \tilde{\mathbf{q}}_{T,f}^{N,t+\Delta t} \\ & + \int_{\Omega} (c_f T^{t+\Delta t} \mathbf{q}_f^{t+\Delta t}) \cdot \nabla \mathbf{N} d\Omega - \mathbf{N}^T \tilde{\mathbf{q}}_T^{N,t+\Delta t} + \int_{\Omega} \mathbf{q}_T^{t+\Delta t} \cdot \nabla \mathbf{N} d\Omega \end{aligned} \quad (48)$$

To explicitly write the Jacobian matrix, the derivatives of residuals ( $\mathbf{R}_M$ ,  $R_H$ ,  $R_C$ ,  $R_T$ ) with respect to increments of unknown variables ( $\delta \tilde{\mathbf{u}}, \delta \tilde{P}_f, \delta \tilde{C}, \delta T$ ) must be derived. The accuracy of the derived Jacobian  $\mathbf{K}$  will determine the convergence performance of the global iteration thus influencing the computation efficiency especially in some highly nonlinear problems.<sup>38</sup> Therefore, great care was taken in deriving the Jacobian for the THMC system here. Note that  $\mathbf{R}$  and  $\mathbf{K}$  matrixes contain many definite integral terms over the element. One needs to evaluate these integrals by Gaussian quadrature after mapping them from global coordinates ( $x, y, z$ ) to local reference coordinates ( $\xi, \eta, \zeta$ ) under the isoparametric element scheme. The final expressions of  $\mathbf{R}$  and  $\mathbf{K}$  are summarized in Appendix A. They are then coded in the UEL to be used together with Abaqus Standard to achieve monolithic solution of THMC problems. The user-defined subroutines, the input files of the verification/validation tests presented in Sections 4 and 5, and an instruction manual are available through the [Supplementary materials](#) associated with this paper.

## 4 | VERIFICATION TESTS

Considering the large size and the highly coupled nature of the system, the development and verification of the UEL shall follow a step-by-step strategy from the simple HM model to the THM model, and finally the comprehensive THMC model. Existing coupled HM and THM problems that have closed-form solutions include: (1) Terzaghi's one-dimensional (1D) consolidation<sup>39</sup>; (2) Mandel's problem<sup>40</sup>; (3) thermoporoelastic bar subjected to temperature change on one end<sup>41</sup>; (4) cylindrical heat source in infinite porous medium.<sup>42</sup> Some of these solutions are based on assumptions and constitutive laws that differ from the ones adopted in this study. In order to verify our UEL which uses a specific thermoporoelastic model of Coussy<sup>24</sup> some of the aforementioned analytical solution must be revisited. In what follows, we will rederive the analytical solutions for problems #1 and #3 and refer to the solution of Cheng and Detournay<sup>43</sup> and McTigue<sup>41</sup> for problems #2 and #4, respectively. Finally, the THMC coupling will be examined through testing chemical species migration along a 1D thermoporoelastic bar.

**FIGURE 3** Schematic diagram for 1D consolidation of a saturated porous column.

#### 4.1 | Test #1 (HM): one-dimensional consolidation

Consider the classical 1D consolidation problem: a saturated porous layer with thickness  $H_{dr}$  for the one-way drainage condition subjected to constant vertical loading as shown in Figure 3. Displacement and pore water flow is permitted only along the vertical direction. The celebrated solution by Terzaghi<sup>39</sup> assumes incompressible fluid and solid grain which is apparently no longer valid in Coussy's poroelasticity and thus requires a revisit. In the absence of thermal effect, fluid density evolution Equation (29) reduces to:

$$\dot{\rho}_f = \rho_f \dot{P}_f / K^f \quad (49)$$

Substituting Equations (49) and (22) into the fluid mass balance Equation (4) and trimming all thermal related terms gives:

$$b\dot{\epsilon}_v + \left( \frac{1}{N} + \frac{n}{K^f} \right) \dot{P}_f + \frac{1}{\rho_f} \nabla \cdot \mathbf{q}_f = 0 \quad (50)$$

Under 1D condition, volumetric strain equals to vertical strain  $\dot{\epsilon}_v = \dot{\epsilon}_{xx} = (\dot{\sigma}_{xx} + b\dot{P}_f)/M$  according to Equation (21), where  $M = K + 4G/3$  is the constrained modulus of porous medium. Using this relation to eliminate  $\dot{\epsilon}_v$  and supply the Darcy's law Equation (25) into Equation (50), the PDE for 1D consolidation problem can be expressed as:

$$\frac{\partial P_f}{\partial t} = -\frac{b\mu}{Mk} C_v \frac{\partial \sigma_{xx}}{\partial t} + C_v \frac{\partial^2 P_f}{\partial x^2} \quad (51)$$

or

$$\frac{\partial P_f}{\partial t} = C_v \frac{\partial^2 P_f}{\partial x^2} \quad (52)$$

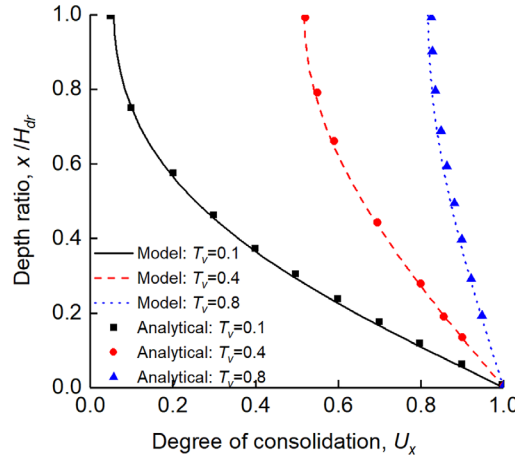

FIGURE 4 1D consolidation simulation results vs. analytical solution.

considering the case of constant total vertical load (i.e.,  $\partial\sigma_{xx}/\partial t = 0$  for  $t > 0$ ). Here the pore fluid pressure  $P_f(x, t)$  is the only unknown and  $C_v$  is the updated coefficient of consolidation:

$$C_v = \frac{k}{\mu \left( \frac{1}{N} + \frac{n}{K_f} + \frac{b^2}{M} \right)} \quad (53)$$

Equation (52) is formally identical to Terzaghi's consolidation equation and its solution can be readily achieved by using the updated coefficient of consolidation  $C_v$  in Terzaghi's solution. Numerical wise, a 10 m-high porous column is modeled in Abaqus as shown in Figure 3. The top boundary is set as drained and subjected to a constant surface pressure of 5 KPa. The bottom and the four lateral boundaries are all constrained along its normal direction with an impermeable surface. The initial pore pressure for the entire porous column is zero and stress free. At  $t = 0$ , a vertical stress of 8 KPa is applied at the top boundary. Other parameters used are:  $E = 10$  MPa;  $\nu = 0.3$ ;  $k = 1 \times 10^{-15}$  m<sup>2</sup>;  $\mu = 0.001$  Pa s;  $\rho_s = 1.25 \times 10^3$  kg/m<sup>3</sup>;  $\rho_f = 1.0 \times 10^3$  kg/m<sup>3</sup>;  $\phi_0 = 0.2$ ;  $K_f = 2000$  MPa;  $N = 100$  MPa;  $b = 0.9$ .

The solution of Equation (52) and the FE results are plotted together in Figure 4 in terms of dimensionless time factor  $T_v = C_v t / H_{dr}^2$ , dimensionless depth  $\bar{x} = x / H_{dr}$ , and degree of consolidation  $U_x = [P_{f0} - P_f(x, t)] / P_{f0}$ , where  $P_{f0}$  is the initial pore pressure. The perfect agreement between the numerical and the analytical solutions verifies the coupled HM capability of the UEL in a 1D setting.

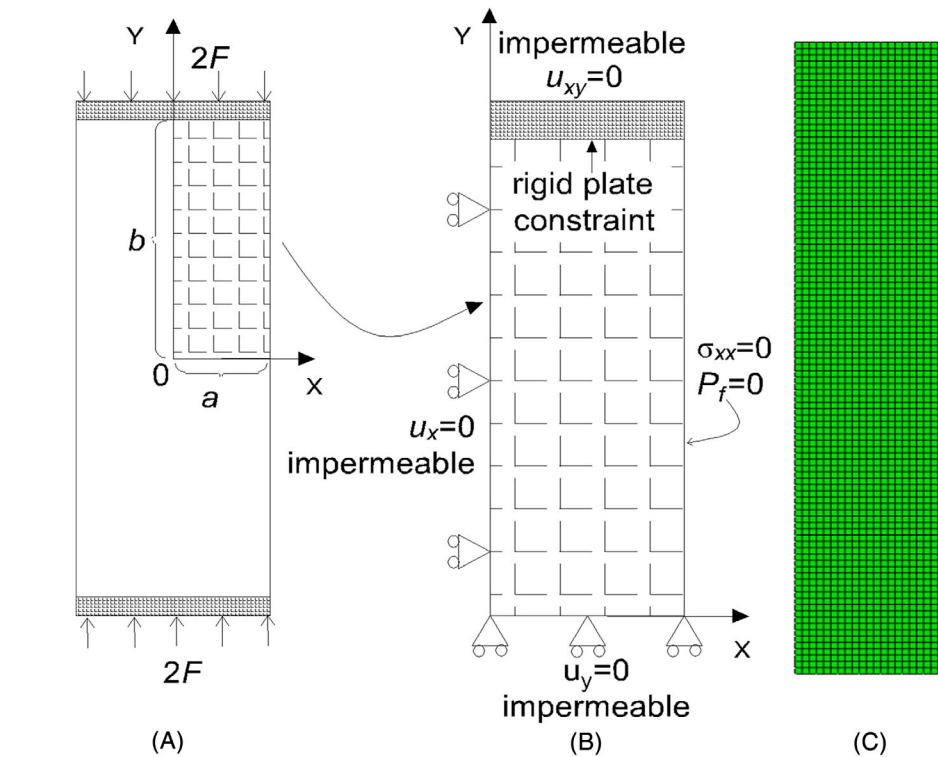

## 4.2 | Test #2 (HM): Mandel's problem

The second example aims to verify the HM coupling capability in 2D scenarios. We chose the Mandel's problem which consists of a  $2a \times 2b$  porous rectangular sample sandwiched by two rigid, frictionless, and impermeable plates resulting a reaction force of  $2F$  as shown in Figure 5. The sample is fully drained and stress free along the horizontal direction. Solution of the Mandel's problem given by Coussy<sup>24</sup> is derived for constant-force condition. This means the top boundary is force-controlled and meanwhile can only have uniform vertical displacement. Numerically, only a quarter of the sample is simulated by the UEL to reduce computational cost as illustrated by Figure 5. The following initial and boundary conditions are enforced on the quarter domain:

$$\begin{cases} \mathbf{u}(x, y, 0) = 0, P_f(x, y, 0) = 0; & 0 < x < a, 0 < y < b \\ u_x(0, y, t) = 0, \mathbf{q}_f(0, y, t) = 0; & t > 0, 0 < y < b \\ u_y(x, 0, t) = 0, \mathbf{q}_f(x, 0, t) = 0; & t > 0, 0 < x < a \\ \sigma_{xx}(a, y, t) = 0, P_f(a, y, t) = 0; & t > 0, 0 < y < b \\ \sigma_{yy}(x, b, t) = F/a, u_{xy}(x, b, t) = 0, \mathbf{q}_f(x, b, t) = 0; & t > 0, 0 < x < a \end{cases} \quad (54)$$

**FIGURE 5** Schematics of Mandel's problem<sup>44</sup> and the finite element model.

**FIGURE 6** Pressure distribution from Abaqus + UEL simulation and analytical solution.<sup>43</sup>

The major challenge in numerical realization of this problem is the reproduction of the uniform vertical displacement on the top boundary in a force-controlled mode. The rigid upper plate cannot be easily represented, as the interaction between a rigid frictionless shell and a user-defined porous medium always induce numerical difficulties. The method adopted here is to approximate the top surface with a constant-pressure boundary, and at the same time using a sufficiently slender domain (low width-to-height ratio) to minimize the impact of unevenly distributed displacement at the top surface. It is found that when the width-to-height ratio reaches 0.2, the results become insensitive to further changes of the geometry. Figure 6 plots the UEL results together with the analytical solution by Cheng and Detournay<sup>43</sup> Here the same poromechanical parameters as the previous verification test are used. Pressure is normalized by its initial value and the dimensionless time is defined as  $\bar{t} = C_v t / a^2$  where  $C_v$  is defined in Equation (53). A satisfactory agreement is observed, confirming the HM capability of the UEL. It is worth noting that at early stage ( $\bar{t} = 0.01, \bar{t} = 0.1$ ), the pore pressure at the central region rises above the initial value even when the lateral boundaries are drained. This signature feature of Mandel's problem is due to poroelastic effect at the system level, which is also successfully captured by the numerical model.

### 4.3 | Test #3 (THM): heating a 1D thermoporoelastic bar

Consider a semi-infinite thermoporoelastic bar, initially at a uniform temperature and pore pressure, subjected to a sudden temperature increase  $T^d$  at the boundary  $x = 0$ . This boundary then remains drained and stress-free. The initial and boundary condition is defined as

$$\begin{cases} \sigma_{xx}(x, 0) = P_f(x, 0) = T(x, 0) = 0; x > 0 \\ u(0, t) = P_f(0, t) = 0, T(0, t) = T^d; t > 0 \end{cases} \quad (55)$$

McTigue<sup>41</sup> provided a solution for this problem but again with a different set of constitutive relations. A new closed-form solution consistent with the proposed governing equations therefore must be developed for verification purpose. Substituting the Darcy's law Equation (25) into the mass balance of fluid Equation (4) yields

$$\rho_f \dot{n} + n \frac{\dot{P}_f \rho_f}{K_f} - 3n\alpha_f \rho_f \dot{T} + n\rho_f \dot{\epsilon}_v - \rho_f \frac{k}{\mu} \nabla^2 P_f = 0 \quad (56)$$

Define  $\alpha_m = \alpha_\phi + n\alpha_f$ , consider porosity evolution from Equation (22), and substitute them into Equation (56):

$$b\dot{\epsilon}_v - 3\alpha_m \dot{T} + \left( \frac{1}{N} + \frac{n}{K_f} \right) \dot{P}_f - \frac{k}{\mu} \nabla^2 P_f = 0 \quad (57)$$

Simplifying the constitutive law Equation (21) for 1D case and considering the stress boundary condition, the volumetric strain increment can be expressed as:

$$d\epsilon_v = d\epsilon_{xx} = \frac{b dP_f + 3\alpha K dT}{M} \quad (58)$$

Substituting Equation (58) into Equation (57) gives:

$$\frac{1}{C_v} \frac{\partial P_f}{\partial t} + A \frac{\partial T}{\partial t} = \frac{\partial^2 P_f}{\partial x^2} \quad (59)$$

where

$$A = \frac{\mu}{k} \left( \frac{3\alpha b K}{M} - 3\alpha_m \right) \quad (60)$$

and  $C_v$  is the same as defined in Equation (53). Introducing normalized variables  $\bar{P}_f = P_f/P_f^d$  and  $\bar{T} = T/T^d$ , where  $T^d$  is the prescribed temperature at  $x = 0$  and  $P_f^d$  is defined such that  $C_v A T^d / P_f^d = 1$ , Equation (59) now reduces to a standard wave equation:

$$\frac{\partial \bar{P}_f}{\partial t} + \frac{\partial \bar{T}}{\partial t} = C_v \frac{\partial^2 \bar{P}_f}{\partial x^2} \text{ and } P_f^d = C_v A T^d \quad (61)$$

On the other hand, the energy balance equation can be rewritten in terms of normalized variables by substituting Equations (27) and (58) into Equation (16) and considering 1D scenario:

$$B \frac{\partial \bar{P}_f}{\partial t} + \frac{\partial \bar{T}}{\partial t} + D \frac{\partial (c_f T \mathbf{q}_f)}{\partial x} = E \frac{\partial^2 \bar{T}}{\partial x^2} \quad (62)$$

FIGURE 7 Finite element model of a 1D thermoporoelastic bar.

where

$$B = \frac{\left[ c_f \rho_f T \left( \frac{1}{N} + \frac{n}{K_f} \right) + \frac{(bc_f \rho_f - c_s \rho_s) T b}{M} \right] P_f^d}{\left[ c_b - 3 \rho_f c_f \alpha_m T + \frac{3(bc_f \rho_f - c_s \rho_s) \alpha K T}{M} \right] T^d} \quad (63)$$

$$D = \frac{1}{\left[ c_b - 3 \rho_f c_f \alpha_m T + 3(bc_f \rho_f - c_s \rho_s) \alpha K T / M \right] T^d} \quad (64)$$

$$E = \frac{\kappa}{c_b - 3 \rho_f c_f \alpha_m T + 3(bc_f \rho_f - c_s \rho_s) \alpha K T / M} \quad (65)$$

and  $c_b = (1 - n) \rho_s c_s + n \rho_f c_f$  is the bulk heat capacity per unit volume of porous media.

For typical values of parameters for geomaterials, the coefficients  $B$  and  $D$  are usually quite small and can be neglected,<sup>24,41</sup> reducing Equation (62) into:

$$\frac{\partial \bar{T}}{\partial t} = E \nabla^2 \bar{T} \quad (66)$$

This conveniently decouples the heat equation Equation (16) from the H or M processes so that it can be solved separately. The analytical solution to Equation (66) associated with the initial boundary conditions Equation (55) is given by:

$$\bar{T} = 1 - \operatorname{erf} \left( \frac{x}{2\sqrt{Et}} \right) \quad (67)$$

Substituting Equation (67) into Equation (61), the problem reduces to a standard parabolic PDE with respect to the normalized fluid pressure  $\bar{P}_f$ , the solution of which under condition (55) is given by:

$$\bar{P}_f = - \left( 1 - \frac{C_v}{E} \right)^{-1} \left[ \operatorname{erf} \left( \frac{x}{2\sqrt{C_v t}} \right) - \operatorname{erf} \left( \frac{x}{2\sqrt{Et}} \right) \right] \quad (68)$$

The finite element model corresponding to this problem is shown in Figure 7. To approximate the semi-infinite condition, the length-to-width ratio of model is made sufficiently large as 100. Lateral surfaces are impermeable, adiabatic, and can only move along the  $x$ -direction to ensure 1D condition. Initially, both  $P_f$  and  $T$  are zero everywhere. The left end is fixed, drained, and subjected to a constant temperature  $T^d = 1$  K. The right end is drained, constant temperature and stress free. All hydromechanical parameters are still the same with the verification test #1. The thermal parameters are specified as:  $c_s = 800$  J/(kg K);  $c_f = 4000$  J/(kg K);  $\alpha = 1.0 \times 10^{-4}$  K<sup>-1</sup>;  $\alpha_f = 3.0 \times 10^{-4}$  K<sup>-1</sup>;  $\alpha_\phi = 0.4 \times 10^{-4}$  K<sup>-1</sup>.

The numerical results and the analytical solutions are plotted in Figures 8 and 9 in terms of normalized temperature  $\bar{T}$ , normalized pore pressure  $\bar{P}_f$ , and normalized  $x$ -coordinate  $\bar{x} = x / \sqrt{C_v t}$  for different values of  $R$  which is defined as the ratio between the diffusion coefficient in Equation (53) and the thermal coefficient in Equation (65) (i.e.,  $R = C_v / E$ ). Thermal conductivity coefficient  $\kappa$  is determined as ( $\kappa = 91.3, 11.4, 5.7$  W/(m K)) corresponding to the selected  $R$  values

FIGURE 8 Normalized temperature profile at  $t = 1.12 \times 10^6$  s.

FIGURE 9 Normalized pressure profile at  $t = 1.12 \times 10^6$  s.

( $R = 0.25, 2, 4$ ) in respect. Perfect agreements between the FE model and the analytical solution are observed at a random time  $t = 1.12 \times 10^6$  s regardless of the choice of  $R$  in this 1D THM coupling analysis.

#### 4.4 | Test #4 (THM): cylindrical heat source in an infinite space

For 3D THM verification, we investigate the problem of cylindrical heat source embedded in an infinite space. This geometry has been studied by Booker and Savvidou<sup>42</sup> to represent the problem of a canister of radioactive waste buried in saturated soil. The finite element mesh is shown in Figure 10. A constant heat flux is applied on the heat source region marked in red. All five boundary surfaces are fixed in its normal direction. Fully drained and constant temperature boundary conditions are assigned to the exterior surface (i.e., ECD and ABED). Because the model represents a one-eighth of the full domain, the interior surfaces (i.e., OADC, OCEB, and OAB) in the current model are all undrained and adiabatic. Final parameters used in verification is the same with test #3 except for  $\kappa = 1.14 \times 10^{-2}$  W/(m K). The power of the heat source is specified as  $1 \text{ W/m}^3$ .

In Figures 11 and 12, the temperature and pressure histories are compared with analytical solutions respectively, at three locations ( $r_0$ ,  $2r_0$ , and  $5r_0$ ) away from the heat source where  $r_0$  is the radius of the canister. The temperature is normalized by a maximum value  $T_N$  at the midpoint on the surface of the heat source; pressure is normalized by  $P_N$ , which represents

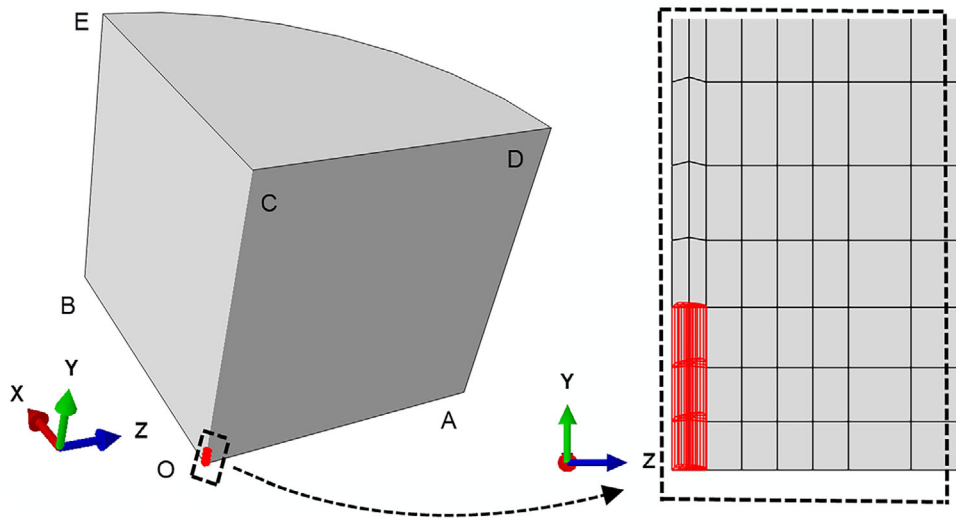

FIGURE 10 Finite element model of an axisymmetric domain containing a cylindrical heat source.

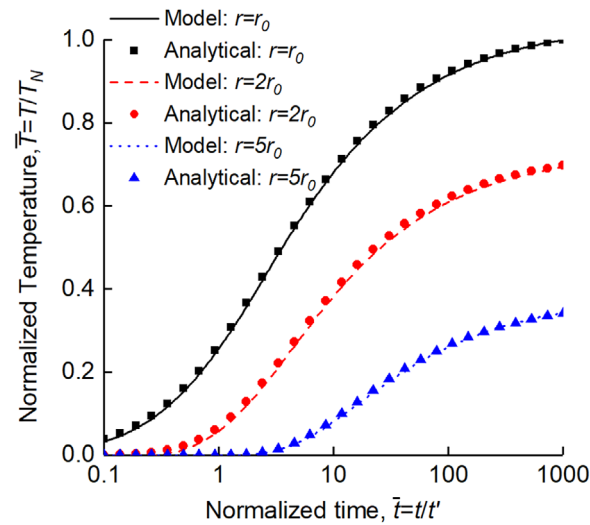

FIGURE 11 Temperature evolution near a cylindrical heat source (analytical solution from Booker and Savvidou<sup>42</sup>).

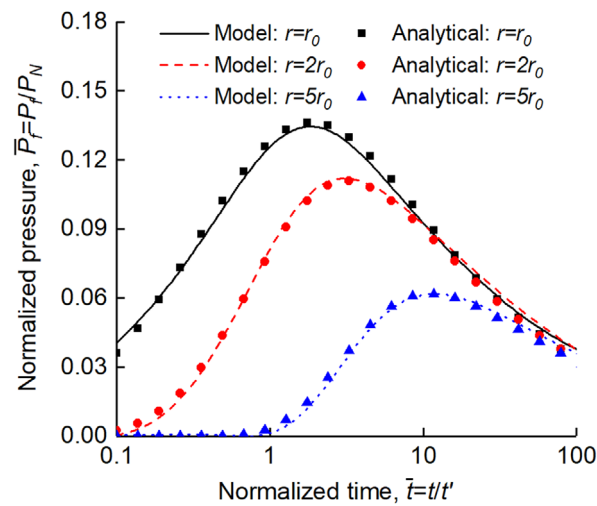

FIGURE 12 Pore pressure evolution near a cylindrical heat source (analytical solution from Booker and Savvidou<sup>42</sup>).

the maximum pressure if soil is impermeable ( $C_v = 0$ ). Time scale is also normalized by a factor  $t' = r_0^2/\kappa$ . The agreements for the temperature and pore pressure histories are excellent at all locations. This agreement, together with the previous three verification results, confirms that the THM governing equations are correctly solved by the UEL.

#### 4.5 | Test #5 (H-C): chemical species migration along a 1D thermoporoelastic bar

Verification of the UEL is not complete until the THM-C coupling is checked. Most past studies end their verification up to THM coupling, given the challenges involved in deriving closed-form solutions when chemical processes present. The current formulation assumes one-way coupling between THM and C, which entails a decoupled solution scheme where chemical molar concentration can be computed independently after the THM fields have been solved or prescribed. Considering the THM part has already been verified, the task here is to focus on verifying the HC coupling capability. Let us inspect chemical field equation first:

$$n\dot{C} + C\dot{n} + (Cn)\dot{\varepsilon}_v + \nabla \cdot \left( \frac{C}{\rho_f} \mathbf{q}_f \right) + \nabla \cdot (\mathbf{q}_C) = 0 \quad (69)$$

Since  $\dot{n} = (b - n)\dot{\varepsilon}_v + \frac{1}{N}\dot{P}_f - 3\alpha_\phi\dot{T}$ ,  $\dot{\varepsilon}_v = \frac{b\dot{P}_f + 3\alpha_K\dot{T}}{M}$  and  $\mathbf{q}_C = -D_C\nabla C$ , Equation (69) can be reorganized for 1D condition as:

$$C \left( \frac{b^2}{M} + \frac{1}{N} \right) \dot{P}_f + 3C \left( \alpha b \frac{K}{M} - \alpha_\phi \right) \dot{T} + n\dot{C} + \frac{\partial}{\partial x} \left( \frac{C}{\rho_f} \mathbf{q}_f \right) = D_C \frac{\partial^2 C}{\partial x^2} \quad (70)$$

Following the same normalization approach in Section 4.2.2 such that  $P_f = P_f^d \bar{P}_f$ ,  $T = T^d \bar{T}$  and  $C = C^d \bar{C}$ , a dimensionless expression for Equation (70) follows:

$$H \frac{\partial \bar{P}_f}{\partial t} + I \frac{\partial \bar{T}}{\partial t} + \frac{\partial \bar{C}}{\partial t} + \frac{\partial}{\partial x} (L \mathbf{q}_f \bar{C}) = R \frac{\partial^2 \bar{C}}{\partial x^2} \quad (71)$$

where

$$H = \left( \frac{b^2}{Mn} + \frac{1}{Nn} \right) \bar{C} P_f^d \quad (72)$$

$$I = 3 \frac{Kb\alpha - M\alpha_\phi}{Mn} \bar{C} T^d \quad (73)$$

$$L = \frac{1}{n\rho_f} \quad (74)$$

$$R = \frac{D_C}{n} \quad (75)$$

For the case of steady-state  $\bar{P}_f$  and  $\bar{T}$  profiles (i.e.,  $\partial \bar{P}_f / \partial t = 0$  and  $\partial \bar{T} / \partial t = 0$ ), Equation (71) reduces to an inhomogeneous convection-diffusion equation describing solute transport.

$$\frac{\partial \bar{C}}{\partial t} = R \frac{\partial^2 \bar{C}}{\partial x^2} - L \mathbf{q}_f \frac{\partial \bar{C}}{\partial x} - \bar{C} \frac{\partial}{\partial x} (L \mathbf{q}_f) \quad (76)$$

Equation (76) is coupled with H through the advective term  $L \mathbf{q}_f \bar{C}$  (or  $v_f \bar{C}$  at 1D condition and  $v_s = 0$ ) originated from the motion of the solute-carrying fluid.<sup>45</sup> In predicting the transport of radio nuclide over a long time-span, the validity of solution will be impaired if the contribution of advection is neglected.<sup>46</sup> Great efforts have been made in the past decades to develop solution to convection-diffusion-reaction (CDR) equations from the condition of constant velocity<sup>47</sup> to spatially

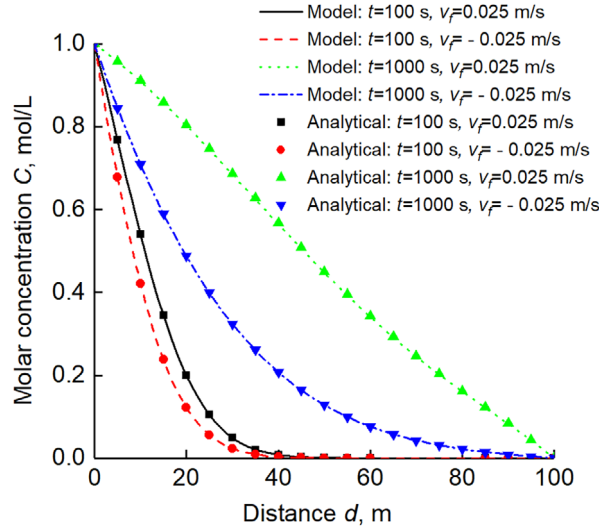

FIGURE 13 Distribution of species molar concentration in a 1D porous bar (analytical solution from Zoppou and Knight<sup>49</sup>).

dependent velocity.<sup>48,49</sup> Considering an initial and boundary condition as follows:

$$\begin{cases} C(x, 0) = 0, P_f(x, 0) = 0, T = 1K, 0 < x < l \\ C(0, t) = C^d, \text{mol/L}, v_f(0, t) = \frac{\pm 0.025m}{s}; t > 0 \\ C(l, t) = 0, v_f(l, t) = \frac{\mp 0.025m}{s}; t > 0 \end{cases} \quad (77)$$

Zoppou and Knight<sup>49</sup> provides solution for this type of unsteady hyperbolic PDE in 1D finite domain, which will be used for comparison with numerical results given by the UEL.

$$\bar{C}(x, t) = \frac{1}{2} \operatorname{erfc} \left( \frac{x - v_f t}{2\sqrt{Rt}} \right) + \frac{1}{2} \exp \left( \frac{v_f x}{R} \right) \operatorname{erfc} \left( \frac{x + v_f t}{2\sqrt{Rt}} \right) \quad (78)$$

The simulation is built on the same geometry and mesh used for the verification test #3 (Section 4.2.1). All hydromechanical parameters remain the same. The chemical diffusion coefficient  $D_c$  is set to  $0.2 \text{ m}^2/\text{s}$ . For the initial condition, we let  $P_f = 0 \text{ MPa}$  and  $C = 0 \text{ mol/L}$  everywhere in the domain. A constant contaminant molar concentration ( $0 \text{ mol/L} \rightarrow 1 \text{ mol/L}$ ) and a constant fluid flux  $q_f$  is then enforced on the left and right end of domain for  $t > 0$ . Since all lateral surfaces are impermeable, mass transfer is constrained in the  $x$ -direction. The resultant  $C$  profiles under different imposed flow rates at different times are plotted in Figure 13. It is obvious that the chemicals transport faster when the bulk fluid flow direction is aligned, and the process is retarded when the bulk flow is against the direction of concentration gradient drop. This implies that advection can greatly facilitate species migration near underground HLW repositories as the concentration and pressure gradients are always aligned. This coupling between H and C during mass transfer is expected and is encoded in the governing equations. Finally, the excellent match between the numerical and the analytical solutions presented in Figure 13 certifies the successful realization of HC coupling by the UEL. Combining the THM and HC verification results, it is confirmed that the developed THMC UEL has correctly implemented the governing equations and can now be applied for full-scale case studies.

## 5 | SIMULATION OF THE ATLAS *IN-SITU* TEST

### 5.1 | ATLAS experiment

Many in-situ tests have been conducted in the past decades to study the THM responses of host rocks due to heating generated by HLW canisters. One of them is the Admissible Thermal Loading for Argillaceous Storage (ATLAS) test

FIGURE 14 Schematic view of the HADES underground research facility in Mol, Belgium.<sup>25</sup>

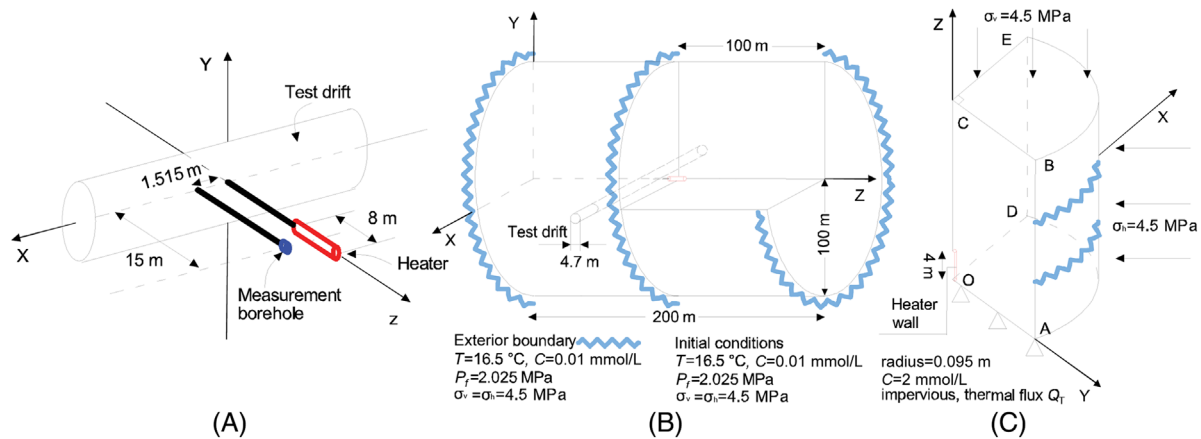

FIGURE 15 Thermal loading history of the heater.

conducted in the underground research facility HADES-URF (see Figure 14) in Mol, Belgium at a depth of 223 m.<sup>50</sup> The host formation, Boom clay, is an over-consolidated clay whose behavior can be roughly captured by thermo-elasticity in the small-strain regime.<sup>10,50</sup> The ATLAS experiment consists of a horizontal main borehole (length = 19 m, diameter = 0.19 m) drilled from the test drift (diameter = 3.5–4.7 m), with electrical heaters installed in the last 8 m of borehole.<sup>51</sup> According to François et al.,<sup>50</sup> the first heating phase happened in July 1993 with the power of 900 W. About 3 years later, the second heating phase started by a sudden increase of the power to 1800 W. The test is then terminated one year later followed by a natural cooling phase. Figure 15 presents the history of heat flux from heaters on the main borehole.

## 5.2 | Numerical simulation setup

Figure 16A sketches the dimensions of the ATLAS test. The main borehole was accompanied by two parallel boreholes with instrumentation installed at 15 m away from the test drift. One of the observation boreholes (AT85E), was drilled 1.515 m away from the main borehole in the same horizontal plane, which is used to record changes in temperature, pore water pressure and total stress.<sup>52</sup> For numerical analysis here, the domain of interest is bounded by a 3D axisymmetric cylindrical surface (diameter = height = 200 m) with the heater located at the center (Figure 16B). At such a large scale, the disturbance of the THM field by the test drift which only occupies a small volume (3.5~4.7 m in diameter) can be neglected. Therefore, the problem is approximately axisymmetric, and only one-eighth of the domain is simulated in the FE model (Figure 16C).

Although the ATLAS test was designed to monitor the coupled THM processes in the host formation, our simulation will also examine the spread of containment species following a hypothetical leakage event at  $t = 0$ . Given the lack of

leakage events documented in the literature for a realistic case study, the purpose of simulating a hypothetical leakage is merely to show the capability of the UEL in handling a full THMC boundary value problem. The boundary conditions for displacement (M), thermal flux (T), water flux (H), and species concentration (C) are applied at the heater-rock interface marked with red color in Figure 16C. Note that the heater itself is not directly simulated in the FE model. To replicate the full loading history in ATLAS, the imposed thermal flux  $Q_T$  is made consistent with the thermal loading history presented in Figure 15. The hypothetical leakage event is simulated by imposing a constant molar concentration ( $C = 2\text{ mmol/L}$ ) of the contaminate species at the heater's surface. The outer boundary of the domain ABDE and BCE (highlighted by blue wavy lines in Figure 16C) are water/chemical permeable, heat conducting, and pressurized by in-situ geostatic stresses (i.e.,  $P_f = 2.025\text{ MPa}$ ,  $C = 0.01\text{ mol/L}$ ,  $T = 16.5^\circ\text{C}$ ,  $\sigma_v = \sigma_h = 4.5\text{ MPa}$ ). The symmetric boundaries OABC, ODEC and OAD are fixed in normal direction with no water, chemical and thermal fluxes allowed.

The THMC parameters used for numerical modeling are presented in Table 2. The THM parameters are selected according to the reported properties for Boom clay in ATLAS experiments<sup>10,51</sup> and the typical values of thermoporoelastic properties for geomaterials summarized in Coussy.<sup>24</sup> The chemical diffusivity is estimated based on the effective diffusion coefficients for dissolved species in Boom Clay measured by Jacobs et al.<sup>53</sup> In the Abaqus, the FE mesh is assigned with the

FIGURE 17 Temperature evolution at the measurement borehole (experiment data from François et al.<sup>50</sup>).

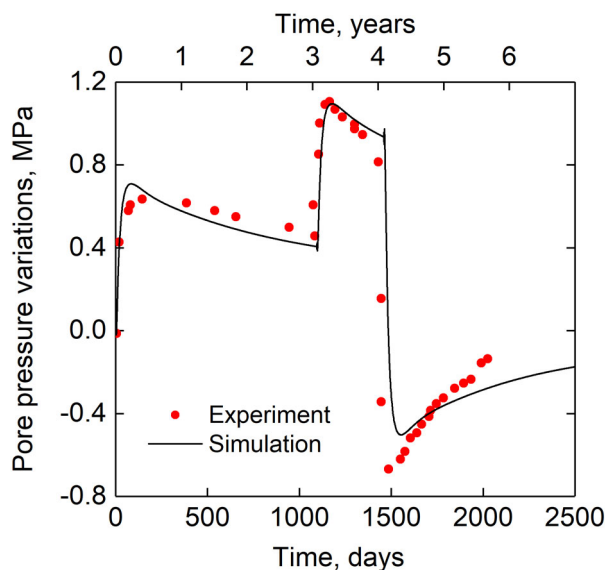

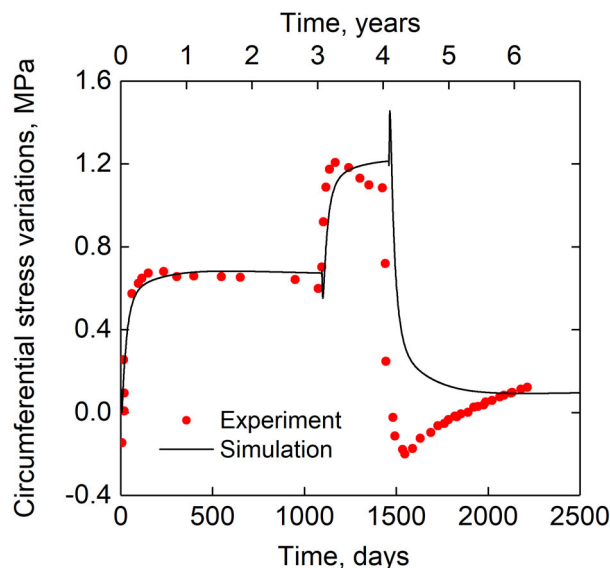

FIGURE 18 Pore pressure evolution at the measurement borehole (experiment data from François et al.<sup>50</sup>).

developed THMC UEL. An element located 1.42 m away from the heater surface will play the role of measurement borehole in the model. The values of field variables extracted from this element will be used for benchmarking and inferring contaminant condition along with all near field nodes.

### 5.3 | Results and discussion

The comparison between the results obtained from the current study and ATLAS experiment are presented in Figures 17–19. Figure 17 shows the temperature variation history at measurement point in 2500 days caused by the prescribed heating history described in Figure 15. The simulated results are in good agreement with experiment data, indicating that heat transfer occurring at the near field is well captured by current model. Figure 18 compares the predicted thermal-induced pore pressure variation with the field data. It is observed that, during the first heating phase, pressure surge rapidly at the beginning and then smoothly dropped even the power of the heater is kept same. Similar

**FIGURE 19** Circumferential stress variation at the measurement borehole (experiment data from François et al.<sup>50</sup>).

response occurs in the second heating phase except with a slightly steeper tendency in decline. The pore pressure rapidly reduces after the heater is turned off, and then gradually dissipates in the remaining time. Overall, the predicted pressure history matches well with the measured data in terms of the aforementioned pressure change characteristics. The slight discrepancy between the predicted and the measured minimum pore pressure (around  $t = 1500$  days) may be remediated by incorporating more physics in the governing equations (e.g., temperature dependency of the dynamic viscosity). Our parametric study (not shown here) also suggests that thermal-induced pressurization is positively correlated with thermal expansion coefficient ( $\alpha_f$ ), while inversely dependent on the fluid flux rate ( $q_f$ ), and the compressibility of the pore fluid ( $1/K_f$ ) and the porous material ( $1/G$  and  $1/K$ ).

Figure 19 presents the predicted and the measured variations of total circumferential stress with time. The agreement is satisfactory during the first heating phase. However, the simulated results start to deviate from the field data near the end of the second heating and the cooling phases. A closer observation shows that the predicted stress increases or maintains relatively constant during heating and monotonically decreases in cooling, while the field data suggests some degree of stress relaxation in heating and stress restoration in cooling. Similar discrepancy has been reported in other numerical simulation of the ATLAS test,<sup>54</sup> but no consensus has arrived regarding its causes yet.<sup>50</sup> Bernier and Neerdael<sup>55</sup> suggested that such deviation might be due to thermal interferences on the measurement devices. We suspect that some viscoelastic or viscoplastic deformations<sup>56</sup> have occurred in the Boom clay formation, which caused the relaxation of the thermal-induced stresses surrounding the heater. Furthermore, the host rock (Boom Clay) may develop some degree of desaturation under the effect of heating, which may have also contributed to the discrepancy between the model prediction and the field data.

Figure 20 shows the time history of contaminant concentration at three locations, following an assumed leakage event at  $t = 0$ . It is apparent that the concentration increases faster close to the canister. Such growth slows down at larger times but still maintains an increasing tendency even at  $t = 2500$  days. Note that oscillations for several curves near  $t = 1000$  days and  $1500$  days are caused by the abrupt change of the heater power at the beginning and the end of the second phase. These sudden changes of the boundary condition are also responsible for the similar oscillations observed in the fluid pressure and the stress histories shown in Figures 18 and 19, respectively. This is a common byproduct of using conventional Galerkin method on transient advection-diffusion problems. Although they disappear in later time steps and are not likely to impair overall results in current case study, the oscillations can be circumvented by adopting advanced finite element methods, such as the Subgrid Scale/Gradient Subgrid Scale (SGS/GSGS) method,<sup>46</sup> Streamline Upwind Petrov-Galerkin (SUPG)<sup>57,58</sup> or Finite Increment Calculus (FIC) procedure.<sup>59</sup>

Figure 21 shows the C distribution along the radius at different times. The model predicts that the contaminant is unlikely to reach 3 m away from the canister after 2500 days, even though the species migration has been accelerated by the advective bulk fluid flow since the beginning of heating. This demonstrates the excellent sealing properties of Boom clay in retarding the leakage of contaminants following a critical event.

## 6 | CONCLUDING REMARKS

In this paper, a THMC UEL with a thermoporoelastic constitutive model is successfully implemented. A comprehensive set of verification tests have been conducted to check the correctness of the implementation at each coupling level. In this process, several analytical solutions are revisited and rederived to be consistent with the specific governing and constitutive equations adopted in this study. The verified UEL is then applied to simulate a full-scale heater test, and the modeling results exhibit good agreement with the field measurements. The ability to simulate diffusion and advection of chemical species coupled with THM loading makes the developed UEL a versatile and efficient tool in addressing geological HLW disposal problems.

The full implementation details including the derivation of governing equations, discretization, residuals, and Jacobian terms are presented. The UEL codes, the input files associated with each verification test and the ATLAS case study, and a user instruction are provided via the [Supplementary Materials](#). We hope the details of the numerical procedure presented here can facilitate the numerical realization of other THMC or general multiphysical solvers. Specifically, expansions can be made regarding the physical processes at concern by upgrading the field equations, material models, and element

types. The Material module unlocks the potential of the code to integrate with advanced constitutive models for more precise modeling of different rock formations. In this regard, the authors is currently implementing a time-dependent microcrack damage model<sup>60</sup> in Material to couple with the proposed THMC UEL with the goal to evaluate the long-term microstructural evolution of host rocks subjected to sustained heating. Another possible extension at the Material level is to incorporate possible coupling between various diffusion mechanisms in the conduction laws (i.e., the generalized Darcy's and Fick's laws<sup>61</sup>). This is important for capturing in coupled mass transport phenomena such as osmotic flow,<sup>62</sup> buoyancy effect,<sup>63</sup> and Soret effect<sup>64</sup> in porous geological materials.

## APPENDIX A: IMPLEMENTATION DETAILS OF THE THMC UEL

### Three dimensional isoparametric element

Over an element  $\Omega^e$ , we define the coordinate mapping using nodal shape functions as follows:

$$\mathbf{x}(\xi) = \mathbf{N}(\xi) \mathbf{x} \quad (\text{A1})$$

where  $\mathbf{N}$  is the shape function matrix,  $\xi = (\xi, \eta, \zeta)$  constitute a reference coordinate system shown in Figure A.

For the three-dimensional 8 node trilinear hexahedral element, the node ordering in the natural coordinates is shown in Figure A. Accordingly, the shape functions for this type of element with respect to the reference coordinates are given by:

$$\begin{cases} N_1 = \frac{1}{8}(1 - \xi)(1 - \eta)(1 - \zeta), N_2 = \frac{1}{8}(1 + \xi)(1 - \eta)(1 - \zeta), \\ N_3 = \frac{1}{8}(1 + \xi)(1 + \eta)(1 - \zeta), N_4 = \frac{1}{8}(1 - \xi)(1 + \eta)(1 - \zeta), \\ N_5 = \frac{1}{8}(1 - \xi)(1 - \eta)(1 + \zeta), N_6 = \frac{1}{8}(1 + \xi)(1 - \eta)(1 + \zeta), \\ N_7 = \frac{1}{8}(1 + \xi)(1 + \eta)(1 + \zeta), N_8 = \frac{1}{8}(1 - \xi)(1 + \eta)(1 + \zeta) \end{cases} \quad (\text{A2})$$

FIGURE A Three dimensional trilinear hexahedral isoparametric reference element.

The infinitesimal strain  $\boldsymbol{\varepsilon}$  can be subsequently defined as:

$$\boldsymbol{\varepsilon} = \begin{bmatrix} \varepsilon_{11} \\ \varepsilon_{22} \\ \varepsilon_{33} \\ \varepsilon_{23} \\ \varepsilon_{13} \\ \varepsilon_{12} \end{bmatrix} = \begin{bmatrix} \frac{\partial}{\partial x} & 0 & 0 \\ 0 & \frac{\partial}{\partial y} & 0 \\ 0 & 0 & \frac{\partial}{\partial z} \\ 0 & \frac{\partial}{\partial z} & \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} & 0 & \frac{\partial}{\partial x} \\ \frac{\partial}{\partial y} & \frac{\partial}{\partial x} & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \nabla_s \mathbf{N} \tilde{\mathbf{u}} \quad (\text{A3})$$

This can be further simplified by relating with Equation (43) as  $\boldsymbol{\varepsilon} = \mathbf{B} \tilde{\mathbf{u}}$ .

### Jacobian

In addition to residuals, the Jacobian terms in Equation (44) are also required by the iterative solver which uses the Newton-Rapson scheme. For conciseness, all kinematics and state variables are referred at the next time step with the notation  $(t+\Delta t)$  omitted.

### Jacobian of M equation

First, recalling Equation (45), the Jacobian for the M equation can be derived as:

$$\begin{aligned} \mathbf{K}_{uu} &= -\frac{\partial \mathbf{R}_M}{\partial \tilde{\mathbf{u}}} = \frac{\partial \int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma} d\Omega}{\partial \tilde{\mathbf{u}}} - \frac{\int_{\Omega} \mathbf{N}^T [n\rho_f + (1-n)\rho_s] \mathbf{g} d\Omega}{\partial \tilde{\mathbf{u}}} \\ &= \int_{\Omega} \mathbf{B}^T \frac{\partial \boldsymbol{\sigma}}{\partial \tilde{\mathbf{u}}} \frac{\partial \tilde{\mathbf{u}}}{\partial \tilde{\mathbf{u}}} d\Omega - \frac{\int_{\Omega} \mathbf{N}^T [n\rho_f + (1-n)\rho_s] \mathbf{g} \frac{\partial n}{\partial \tilde{\mathbf{u}}} d\Omega}{\partial \tilde{\mathbf{u}}} \end{aligned} \quad (\text{A4})$$

Considering  $\mathbf{u} = \mathbf{N}\tilde{\mathbf{u}}$ , we have  $\frac{\partial \mathbf{u}}{\partial \tilde{\mathbf{u}}} = \mathbf{N}$ , then  $\frac{\partial \boldsymbol{\sigma}}{\partial \tilde{\mathbf{u}}} \frac{\partial \mathbf{u}}{\partial \tilde{\mathbf{u}}} = \frac{\partial \boldsymbol{\sigma}}{\partial \boldsymbol{\varepsilon}} \frac{\partial \boldsymbol{\varepsilon}}{\partial \tilde{\mathbf{u}}} \frac{\partial \mathbf{u}}{\partial \tilde{\mathbf{u}}} = \mathbf{D}_{mm} \nabla_s \mathbf{N} = \mathbf{D}_{mm} \mathbf{B}$ . Further noticing  $\frac{\partial n}{\partial \tilde{\mathbf{u}}} = \frac{\partial n}{\partial \boldsymbol{\varepsilon}} \frac{\partial \boldsymbol{\varepsilon}}{\partial \tilde{\mathbf{u}}} = \mathbf{D}_{nm} \frac{\partial (\nabla_s \mathbf{u})}{\partial \tilde{\mathbf{u}}} = \mathbf{D}_{nm} \mathbf{B}$  and  $\mathbf{D}_{nm} = [b - n \ b - n \ b - n \ 0 \ 0 \ 0]$ , Equation (A4) can be rewritten as:

$$\mathbf{K}_{uu} = \int_{\Omega} \mathbf{B}^T \mathbf{D}_{mm} \mathbf{B} d\Omega + (\rho_s - \rho_f) \mathbf{g} \int_{\Omega} \mathbf{D}_{nm} \mathbf{B} d\Omega \quad (\text{A5})$$

where

$$\mathbf{D}_{mm} = \frac{\partial \boldsymbol{\sigma}}{\partial \boldsymbol{\varepsilon}} = \begin{bmatrix} K + \frac{4}{3}G & K - \frac{2}{3}G & K - \frac{2}{3}G & 0 & 0 & 0 \\ K - \frac{2}{3}G & K + \frac{4}{3}G & K - \frac{2}{3}G & 0 & 0 & 0 \\ K - \frac{2}{3}G & K - \frac{2}{3}G & K + \frac{4}{3}G & 0 & 0 & 0 \\ 0 & 0 & 0 & 2G & 0 & 0 \\ 0 & 0 & 0 & 0 & 2G & 0 \\ 0 & 0 & 0 & 0 & 0 & 2G \end{bmatrix}$$

Similarly, for the HM coupling term, we have

$$\begin{aligned} \mathbf{K}_{uP} &= -\frac{\partial R_{\mathbf{M}}}{\partial P_f} = \frac{\partial \int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma} d\Omega}{\partial P_f} - \frac{\partial \int_{\Omega} \mathbf{N}^T \mathbf{b} d\Omega}{\partial P_f} \\ &= \int_{\Omega} \mathbf{B}^T \frac{\partial \boldsymbol{\sigma}}{\partial P_f} \frac{\partial P_f}{\partial P_f} d\Omega - \mathbf{D}_{nh} \int_{\Omega} \mathbf{N}^T \frac{\partial \mathbf{b}}{\partial n} \frac{\partial n}{\partial P_f} \frac{\partial P_f}{\partial P_f} d\Omega \\ &= \int_{\Omega} \mathbf{B}^T \mathbf{D}_{mh} \mathbf{N} d\Omega + (\rho_s - \rho_f) \int_{\Omega} \mathbf{N}^T \mathbf{g} \mathbf{D}_{nh} \mathbf{N} d\Omega \end{aligned} \quad (\text{A6})$$

where  $\mathbf{D}_{mh} = [-b \ -b \ -b \ 0 \ 0 \ 0]^T$  and  $\mathbf{D}_{nh} = \frac{1}{N}$ .

Obviously  $\mathbf{K}_{uC} = 0$  and the last term writes:

$$\begin{aligned} \mathbf{K}_{uT} &= -\frac{\partial R_{\mathbf{M}}}{\partial T} = \frac{\partial \int_{\Omega} \mathbf{B}^T \boldsymbol{\sigma} d\Omega}{\partial T} - \frac{\partial \int_{\Omega} \mathbf{N}^T \mathbf{b} d\Omega}{\partial T} \\ &= \int_{\Omega} \mathbf{B}^T \frac{\partial \boldsymbol{\sigma}}{\partial T} \frac{\partial T}{\partial T} d\Omega - \int_{\Omega} \mathbf{N}^T \frac{\partial \mathbf{b}}{\partial n} \frac{\partial n}{\partial T} \frac{\partial T}{\partial T} d\Omega \\ &= \int_{\Omega} \mathbf{B}^T \mathbf{D}_{mt} \mathbf{N} d\Omega + (\rho_s - \rho_f) \int_{\Omega} \mathbf{N}^T \mathbf{g} \mathbf{D}_{nt} \mathbf{N} d\Omega \end{aligned} \quad (\text{A7})$$

where  $\mathbf{D}_{nt} = -3\alpha_{\phi}$  and  $\mathbf{D}_{mt} = [-3\alpha K \ -3\alpha K \ -3\alpha K \ 0 \ 0 \ 0]^T$ .

### Jacobian of H equation

Recalling Equation (46), the HM coupling Jacobians can be expanded as

$$\mathbf{K}_{Pu} = -\frac{\partial R_H}{\partial \tilde{\mathbf{u}}} = \frac{1}{\Delta t} \frac{\partial \int_{\Omega} \mathbf{N}^T \rho_f [\nabla \cdot (\mathbf{u}^{t+\Delta t}) - \nabla \cdot (\mathbf{u}^t)] d\Omega}{\partial \tilde{\mathbf{u}}} + \int_{\Omega} \mathbf{N}^T \frac{\partial n}{\partial \tilde{\mathbf{u}}} \frac{\rho_f}{K_f} \dot{P}_f d\Omega \quad (\text{A8})$$

Since  $\boldsymbol{\varepsilon}_v = \nabla^T \mathbf{u} = \nabla^T \mathbf{N} \tilde{\mathbf{u}}$  with

$$\begin{aligned} \nabla^T \mathbf{N} &= \begin{bmatrix} \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \end{bmatrix} \begin{bmatrix} N_1 & 0 & 0 & N_2 & 0 & 0 & \dots & N_n & 0 & 0 \\ 0 & N_1 & 0 & 0 & N_2 & 0 & \dots & 0 & N_n & 0 \\ 0 & 0 & N_1 & 0 & 0 & N_2 & \dots & 0 & 0 & N_n \end{bmatrix} = \\ &= \begin{bmatrix} \frac{\partial N_1}{\partial x} & \frac{\partial N_1}{\partial y} & \frac{\partial N_1}{\partial z} & \frac{\partial N_2}{\partial x} & \frac{\partial N_2}{\partial y} & \frac{\partial N_2}{\partial z} & \dots & \frac{\partial N_n}{\partial x} & \frac{\partial N_n}{\partial y} & \frac{\partial N_n}{\partial z} \end{bmatrix} \end{aligned}$$

Equation (A8) can be rewritten as

$$\begin{aligned} \mathbf{K}_{Pu} = -\frac{\partial R_H}{\partial \mathbf{u}} &= \frac{1}{\Delta t} \rho_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nm} \mathbf{B} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T n \rho_f \nabla^T \mathbf{N} d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T \rho_f \dot{\varepsilon}_v \mathbf{D}_{nm} \mathbf{B} d\Omega + \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nm} \mathbf{B} \left( \frac{\rho_f}{K_f} \dot{P}_f - 3\rho_f \alpha_f \dot{T} \right) d\Omega \end{aligned} \quad (\text{A9})$$

Regarding the Jacobian of H equation with respect to pressure, we have

$$\begin{aligned} \mathbf{K}_{PP} = -\frac{\partial R_H}{\partial P_f} &= \frac{\partial \int_{\Omega} \mathbf{N}^T \rho_f \dot{n} d\Omega}{\partial P_f} + \frac{\partial \int_{\Omega} \mathbf{N}^T n (\rho_f \dot{P}_f / K_f - 3\rho_f \alpha_f \dot{T}) d\Omega}{\partial P_f} \\ &+ \frac{\partial \int_{\Omega} \mathbf{N}^T n^{t+\Delta t} \rho_f \dot{\varepsilon}_v d\Omega}{\partial P_f} - \frac{\partial \int_{\Omega} (\nabla \mathbf{N})^T \mathbf{q}_f d\Omega}{\partial P_f} \end{aligned} \quad (\text{A10})$$

According to  $\frac{\partial \int_{\Omega} (\nabla \mathbf{N})^T \mathbf{q}_f d\Omega}{\partial P} = -\int_{\Omega} (\nabla \mathbf{N})^T \frac{\rho_f \kappa}{\mu_d} (\nabla \mathbf{N}) d\Omega$ , Equation (A10) finally gives:

$$\begin{aligned} \mathbf{K}_{PP} = -\frac{\partial R_H}{\partial P_f} &= \frac{1}{\Delta t} \rho_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{B} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T n \frac{\rho_f}{K_f} \mathbf{N} d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{N} \left( \frac{\rho_f}{K_f} \dot{P}_f - 3\rho_f \alpha_f \dot{T} \right) d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{N} \rho_f \dot{\varepsilon}_v (\mathbf{u}^{t+\Delta t}) d\Omega + \frac{\rho_f \kappa}{\mu} \int_{\Omega} (\nabla \mathbf{N})^T (\nabla \mathbf{N}) d\Omega \end{aligned} \quad (\text{A11})$$

Similarly,  $\mathbf{K}_{PC} = 0$  and  $\mathbf{K}_{PT}$  can be written as:

$$\begin{aligned} \mathbf{K}_{PT} = -\frac{\partial R_H}{\partial T} &= \frac{1}{\Delta t} \rho_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nt} \mathbf{N} d\Omega \\ &+ \frac{\rho_f}{K_f} \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nT} \mathbf{N} \dot{P}_f d\Omega - 3\rho_f \alpha_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nT} \mathbf{N} \dot{T} d\Omega \\ &- \frac{3\rho_f \alpha_f}{\Delta t} \int_{\Omega} \mathbf{N}^T n T \mathbf{N} d\Omega + \int_{\Omega} \mathbf{N}^T \rho_f \dot{\varepsilon}_v \mathbf{D}_{nt} \mathbf{N} d\Omega \end{aligned} \quad (\text{A12})$$

### Jacobian of C equation

Considering Equation (47), the first component  $\mathbf{K}_{cu}$  can be derived as:

$$\begin{aligned} \mathbf{K}_{Cu} = -\frac{\partial R_C}{\partial \mathbf{u}} &= \int_{\Omega} \mathbf{N}^T \frac{\partial n}{\partial \mathbf{u}} \dot{C} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T C \frac{\partial n}{\partial \mathbf{u}} d\Omega + \int_{\Omega} \mathbf{N}^T C \frac{\partial n}{\partial \mathbf{u}} \dot{\varepsilon}_v d\Omega \\ &= \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nm} \mathbf{B} \dot{C} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nm} \mathbf{B} d\Omega + \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nm} \mathbf{B} \dot{\varepsilon}_v d\Omega \end{aligned} \quad (\text{A13})$$

Regarding the Jacobian of C equation with respect to pressure, we have

$$\begin{aligned} \mathbf{K}_{CP} &= \frac{\partial \int_{\Omega} \mathbf{N}^T n \dot{C} d\Omega}{\partial P_f} + \frac{\partial \int_{\Omega} \mathbf{N}^T C \dot{n} d\Omega}{\partial P_f} + \frac{\partial \int_{\Omega} \mathbf{N}^T (Cn) \nabla \cdot \mathbf{v}_s d\Omega}{\partial P_f} - \frac{1}{\rho_f} \frac{\partial \int_{\Omega} (C \mathbf{q}_f) \cdot \nabla \mathbf{N} d\Omega}{\partial P_f} \\ &= \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{N} \dot{C} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nh} \mathbf{N} d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nh} \mathbf{N} \dot{\varepsilon}_v d\Omega + \frac{c_f \kappa}{\mu} \int_{\Omega} C (\nabla \mathbf{N})^T \nabla \mathbf{N} d\Omega \end{aligned} \quad (\text{A14})$$

Considering  $\frac{\partial \int_{\Omega} \mathbf{q}_c \cdot \nabla \mathbf{N} d\Omega}{\partial C} = -\int_{\Omega} (\nabla \mathbf{N})^T D_C \nabla \mathbf{N} d\Omega$ ,  $\mathbf{K}_{CC}$  can be written as:

$$\begin{aligned} \mathbf{K}_{CC} = -\frac{\partial R_C}{\partial C} &= \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T n \mathbf{N} d\Omega + \int_{\Omega} \mathbf{N}^T \mathbf{N} \dot{n} d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T n \mathbf{N} \dot{\varepsilon}_v d\Omega - \frac{1}{\rho_f} \int_{\Omega} \mathbf{N}^T \mathbf{q}_f \nabla \mathbf{N} d\Omega + \int_{\Omega} (\nabla \mathbf{N})^T D_C \nabla \mathbf{N} d\Omega \end{aligned} \quad (\text{A15})$$

The last component can be similarly derived as:

$$\mathbf{K}_{CT} = -\frac{\partial R_C}{\partial T} = \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nt} \mathbf{N} \dot{C} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nt} \mathbf{N} d\Omega + \int_{\Omega} \mathbf{N}^T C \mathbf{D}_{nt} \mathbf{N} \dot{\epsilon}_v d\Omega \quad (\text{A16})$$

### Jacobian of T equation

Regarding Equation (48), the TM coupling Jacobians can be expanded as:

$$\begin{aligned} \mathbf{K}_{Tu} &= -\frac{\partial R_T}{\partial \mathbf{u}} = -\rho_s c_s \int_{\Omega} \mathbf{N}^T \frac{\partial n}{\partial \mathbf{u}} \dot{T} d\Omega + \rho_f c_f \int_{\Omega} \mathbf{N}^T \frac{\partial n}{\partial \mathbf{u}} \dot{T} d\Omega \\ &+ \frac{1}{\Delta t} \frac{\partial \int_{\Omega} \mathbf{N}^T [(1-n)\rho_s c_s + n\rho_f c_f] T (\nabla \cdot \mathbf{u}^{t+\Delta t} - \nabla \cdot \mathbf{u}^t) d\Omega}{\partial \mathbf{u}} \\ &+ c_f \rho_f \left( \frac{\dot{P}_f}{K^f} - 3\alpha_f \dot{T} \right) \int_{\Omega} \mathbf{N}^T T \frac{\partial n}{\partial \mathbf{u}} d\Omega - \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T \rho_s c_s \frac{\partial n}{\partial \mathbf{u}} T \dot{\epsilon}_v d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T \rho_f c_f \frac{\partial n}{\partial \mathbf{u}} T \dot{\epsilon}_v d\Omega \\ &= -\rho_s c_s \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nm} \mathbf{B} \dot{T} d\Omega + \rho_f c_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nm} \mathbf{B} \dot{T} d\Omega \\ &+ \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T [(1-n)\rho_s c_s + n\rho_f c_f] T \nabla^T \mathbf{N} d\Omega + c_f \rho_f \left( \dot{P}_f / K^f - 3\alpha_f \dot{T} \right) \int_{\Omega} \mathbf{N}^T T \mathbf{D}_{nm} \mathbf{B} d\Omega \\ &- \int_{\Omega} \mathbf{N}^T \rho_s c_s \mathbf{D}_{nm} \mathbf{B} T \dot{\epsilon}_v d\Omega + \int_{\Omega} \mathbf{N}^T \rho_f c_f \mathbf{D}_{nm} \mathbf{B} T \dot{\epsilon}_v d\Omega \end{aligned} \quad (\text{A17})$$

For the TH coupling term, we have

$$\begin{aligned} \mathbf{K}_{TP} &= -\frac{\partial R_T}{\partial P_f} = -\rho_s c_s \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{N} \dot{T} d\Omega + \rho_f c_f \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nh} \mathbf{N} \dot{T} d\Omega \\ &- \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T T c_s \rho_s \frac{1}{N} \mathbf{N} d\Omega + \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T \dot{T} (c_f \rho_f - c_s \rho_s) \mathbf{D}_{nh} \mathbf{N} d\Omega \\ &+ \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T T c_f n \frac{\rho_f}{K^f} \mathbf{N} d\Omega + c_f \rho_f \left( \dot{P}_f / K^f - 3\alpha_f \dot{T} \right) \int_{\Omega} \mathbf{N}^T T \mathbf{D}_{nh} \mathbf{N} \dot{P}_f d\Omega \\ &+ \int_{\Omega} \mathbf{N}^T [-\rho_s c_s + \rho_f c_f] \mathbf{D}_{nh} \mathbf{N} T \dot{\epsilon}_v d\Omega + \frac{c_f \rho_f \kappa}{\mu} \int_{\Omega} T (\nabla \mathbf{N})^T \nabla \mathbf{N} d\Omega \end{aligned} \quad (\text{A18})$$

Obviously  $\mathbf{K}_{TC} = 0$  and the last term writes:

$$\begin{aligned} \mathbf{K}_{TT} &= -\frac{\partial R_T}{\partial T} = \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T [(1-n)\rho_s c_s + n\rho_f c_f] \mathbf{N} d\Omega - \frac{6c_s \rho_s \alpha}{\Delta t} \int_{\Omega} \mathbf{N}^T T \alpha_{\phi} \mathbf{N} d\Omega \\ &+ (c_f \rho_f - c_s \rho_s) \left( \frac{1}{\Delta t} \int_{\Omega} \mathbf{N}^T T \mathbf{D}_{nT} \mathbf{N} d\Omega + \int_{\Omega} \mathbf{N}^T n \mathbf{N} d\Omega \right) \\ &+ \int_{\Omega} \mathbf{N}^T \mathbf{N} c_f n \rho_f \left( \dot{P}_f / K^f - 3\alpha_f \dot{T} \right) d\Omega + \int_{\Omega} \mathbf{N}^T T \mathbf{D}_{nT} \mathbf{N} c_f \rho_f \left( \dot{P}_f / K^f - 3\alpha_f \dot{T} \right) d\Omega \\ &- \frac{6\rho_f \alpha_f}{\Delta t} \int_{\Omega} \mathbf{N}^T T c_f n \mathbf{N} d\Omega + [(1-n)\rho_s c_s + n\rho_f c_f] \int_{\Omega} \mathbf{N}^T \mathbf{N} \dot{\epsilon}_v d\Omega \\ &+ (\rho_f c_f - \rho_s c_s) \int_{\Omega} \mathbf{N}^T \mathbf{D}_{nT} \mathbf{N} T \dot{\epsilon}_v d\Omega - c_f \int_{\Omega} \mathbf{N}^T (\mathbf{q}_f)^T \nabla \mathbf{N} d\Omega + \int_{\Omega} (\nabla \mathbf{N})^T \kappa (\nabla \mathbf{N}) d\Omega \end{aligned} \quad (\text{A19})$$

### Numerical integration

Targeting at the generalized 3D analysis, a cubic eight-node element (C3D8) with  $2 \times 2 \times 2$  Gaussian quadrature points is employed for numerical integration in terms of an arbitrary function  $f$ :

$$\begin{aligned} \int_{\Omega} f(x, y, z) d\Omega &= \int_{-1}^1 \int_{-1}^1 \int_{-1}^1 \det \mathbf{J} f(\xi, \eta, \zeta) d\xi d\eta d\zeta \\ &\approx \sum_{i=1}^2 \sum_{j=1}^2 \sum_{k=1}^2 W_i W_j W_k \det \mathbf{J} f(\xi, \eta, \zeta) \end{aligned} \quad (\text{A20})$$

where  $\mathbf{J}$  is also called Jacobian matrix in isoparametric mapping defined by:

$$\mathbf{J} = \begin{bmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} & \frac{\partial z}{\partial \xi} \\ \frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} & \frac{\partial z}{\partial \eta} \\ \frac{\partial x}{\partial \zeta} & \frac{\partial y}{\partial \zeta} & \frac{\partial z}{\partial \zeta} \end{bmatrix} \quad (\text{A21})$$

The final expressions of residuals and Jacobians implemented in the UEL are summarized below. Note the surface flux terms in residuals Equations (45)–(48) are excluded in the final implementation since the natural boundary conditions of the M, H, C and T fields applied on  $\partial\Omega_t$  (Equation (31)),  $\partial\Omega_H^N$  (Equation (32)),  $\partial\Omega_C^N$  and  $\partial\Omega_{C,f}^N$  (Equation (33)),  $\partial\Omega_T^N$  and  $\partial\Omega_{T,f}^N$  (Equation (34)) are handled by Abaqus CAE.

$$\begin{aligned} \mathbf{R}_M = & - \sum_{i=1}^2 \sum_{j=1}^2 \sum_{k=1}^2 W_i W_j W_k \det \mathbf{J} \mathbf{B}^T (\xi_i, \eta_j, \zeta_k) \boldsymbol{\sigma} (\xi_i, \eta_j, \zeta_k) \\ & + \sum_{i=1}^2 \sum_{j=1}^2 \sum_{k=1}^2 W_i W_j W_k \det \mathbf{J} \mathbf{N}^T (\xi_i, \eta_j, \zeta_k) [n \rho_f + (1-n) \rho_s] \mathbf{g} \end{aligned} \quad (\text{A22})$$
